

# Package ‘aqp’

November 28, 2023

**Version** 2.0.2

**Title** Algorithms for Quantitative Pedology

**Author** Dylan Beaudette [aut, cre],  
Pierre Roudier [aut, ctb],  
Andrew Brown [aut, ctb]

**Maintainer** Dylan Beaudette <dylan.beaudette@usda.gov>

**Depends** R (>= 3.5.0)

**Imports** grDevices, graphics, stats, utils, methods, grid, lattice,  
cluster, sp, stringr, data.table, farver

**Suggests** colorspace, ape, soilDB, sf, latticeExtra, tactile,  
compositions, sharpshootR, markovchain, xtable, testthat,  
Gmedian, Hmisc, tibble, RColorBrewer, scales, digest, MASS,  
mpspline2, soiltexture, gower, knitr, rmarkdown, plyr

**Description** The Algorithms for Quantitative Pedology (AQP) project was started in 2009 to organize a loosely-related set of concepts and source code on the topic of soil profile visualization, aggregation, and classification into this package (aqp). Over the past 8 years, the project has grown into a suite of related R packages that enhance and simplify the quantitative analysis of soil profile data. Central to the AQP project is a new vocabulary of specialized functions and data structures that can accommodate the inherent complexity of soil profile information; freeing the scientist to focus on ideas rather than boilerplate data processing tasks <doi:10.1016/j.cageo.2012.10.020>. These functions and data structures have been extensively tested and documented, applied to projects involving hundreds of thousands of soil profiles, and deeply integrated into widely used tools such as SoilWeb <<https://casoilresource.lawr.ucdavis.edu/soilweb-apps/>>. Components of the AQP project (aqp, soilDB, sharpshootR, soilReports packages) serve an important role in routine data analysis within the USDA-NRCS Soil Science Division. The AQP suite of R packages offer a convenient platform for bridging the gap between pedometric theory and practice.

**License** GPL (>= 3)

**LazyLoad** yes

**Repository** CRAN

**URL** <https://github.com/ncss-tech/aqp>, <https://ncss-tech.github.io/AQP/>

**BugReports** <https://github.com/ncss-tech/aqp/issues>

**Language** en-US

**Encoding** UTF-8

**RoxygenNote** 7.2.3

**VignetteBuilder** knitr

**NeedsCompilation** no

**Date/Publication** 2023-11-28 05:20:10 UTC

aqp-package

*Algorithms for Quantitative Pedology***Description**

The aqp (Algorithms for Quantitative Pedology) package for R was developed to address some of the difficulties associated with processing soils information, specifically related to visualization, aggregation, and classification of soil profile data. This package is based on a mix of S3/S4 functions and classes, and most functions use basic dataframes as input, where rows represent soil horizons and columns define properties of those horizons. Common to most functions are the requirements that horizon boundaries are defined as depth from 0, and that profiles are uniquely defined by an id column. The aqp package defines an S4 class, "SoilProfileCollection", for storage of profile-level metadata, as well as summary, print, and plotting methods that have been customized for common tasks related to soils data.

**Details**

Demos: `demo(aqp)`

---

accumulateDepths	<i>Accumulate horizon depths, and reflect reversed depths, relative to new datum</i>
------------------	--

---

**Description**

Fix old-style organic horizon depths or depths with a non-standard datum by the "depth accumulation" method.

**Usage**

```
accumulateDepths(
  x,
  id = NULL,
  hzdepths = NULL,
  hzname = NULL,
  hzdatum = 0,
  seqnum = NULL,
  pattern = "0",
  fix = TRUE
)
```

**Arguments**

<code>x</code>	A <code>data.frame</code> or <code>SoilProfileCollection</code>
<code>id</code>	unique profile ID. Default: <code>NULL</code> , if <code>x</code> is a <code>SoilProfileCollection</code> <code>idname(x)</code>
<code>hzdepths</code>	character vector containing horizon top and bottom depth column names. Default: <code>NULL</code> , if <code>x</code> is a <code>SoilProfileCollection</code> <code>horizonDepths(x)</code>
<code>hzname</code>	character vector containing horizon designation or other label column names. Default: <code>NULL</code> , if <code>x</code> is a <code>SoilProfileCollection</code> <code>hzdesgname(x)</code>
<code>hzdatum</code>	a numeric vector to add to accumulated depths. Default: <code>0</code> . Can be equal in length to number of profiles if <code>x</code> is a <code>SoilProfileCollection</code> or number of (unique) IDs if <code>x</code> is a <code>data.frame</code> .

seqnum	Optional: character vector containing record "sequence number" column name; used in-lieu of hzname (when NA) to identify "first" record in a profile
pattern	pattern to search for in hzname to identify matching horizons to append the profile to
fix	apply adjustments to missing (NA) depths and expand 0-thickness horizons? Default: TRUE

### Details

The "depth accumulation" method calculates thicknesses of individual horizons and then cumulative sums them after putting them in id + top depth order. The routine tries to determine context based on hzname and pattern. The main transformation is if a top depth is deeper than the bottom depth, the depths are reflected on the Z-axis (made negative). The data are then id + top depth sorted again, the thickness calculated and accumulated to replace the old depths.

This function uses several heuristics to adjust data before transformation and thickness calculation:

#### Regex matching of horizon designation patterns and similar:

- matches of pattern where both top and bottom depth NA -> [0, 1] [top, bottom] depth
- REMOVE horizons that do not match pattern where both top and bottom depths NA

#### Over-ride hzname handling with the sequence column argument seqnum:

- if seqnum column specified "first record with NA hzname" is considered a pattern match if seqnum == 1

#### Trigger "fixing" with the fix argument::

- Add 1 cm to bottom-most horizons with NA bottom depth
- Add 1 cm thickness to horizons with top and bottom depth equal
- Add 1 cm thickness to horizons with NA top depth and bottom depth 0

### Value

A horizon-level data.frame, suitable for promoting to SPC with depths<-, or a SoilProfileCollection, depending on the class of x.

### Examples

```
# example using hzdatum argument
data(sp4)
depths(sp4) <- id ~ top + bottom
hz <- accumulateDepths(sp4,
  id = "id",
  hzdepths = c("top", "bottom"),
  hzname = "name",
  hzdatum = 5 * 1:length(sp4))

plot(hz)

# example using old-style 0 horizons
hz <- read.table(text = "peidref hzdept hzdepb hzname seqnum phiid")
```

plotSPC(orig0, max.depth = 25)
plotSPC(fixed0, max.depth = 25)

```

---

addBracket

*Add Depth Brackets*

---

## Description

Add depth brackets to soil profile sketches.

## Usage

```

addBracket(
  x,
  label.cex = 0.75,
  tick.length = 0.05,
  arrow.length = 0.05,
  offset = -0.3,

```

```

    missing.bottom.depth = NULL,
    ...
)

```

### Arguments

x	data.frame object containing idname(x), top, bottom, and optionally label columns
label.cex	scaling factor for label font
tick.length	length of bracket "tick" mark
arrow.length	length of arrowhead
offset	left-hand offset from each profile
missing.bottom.depth	distance (in depth units) to extend brackets that are missing a lower depth (defaults to max depth of collection)
...	further arguments passed on to segments or arrows

### Details

x may contain multiple records per profile. Additional examples can be found in [this tutorial](#).

### Note

This is a low-level plotting function: you must first plot a SoilProfileCollection object before using this function.

### Examples

```

# sample data
data(sp1)

# add color vector
sp1$soil_color <- with(sp1, munsell2rgb(hue, value, chroma))

# promote to SoilProfileCollection
depths(sp1) <- id ~ top + bottom

# plot profiles
par(mar = c(0, 0, 0, 1))
plotSPC(sp1, width = 0.3)

```

```

# extract min--max depths associated with all A horizons
# result is a single-row data.frame / profile
combinedBracket <- function(i) {
  h <- horizons(i)
  idn <- idname(i)
  this.id <- h[[idn]][1]

  idx <- grep('^A', h$name)

  res <- data.frame(
    id = this.id,
    top = min(h$top[idx]),
    bottom = max(h$bottom[idx], na.rm=TRUE)
  )
  names(res)[1] <- idn

  return(res)
}

# return matching horizon top / bottom depths for A or C horizons
# result is a 0 or more row data.frame / profile
individualBrackets <- function(i) {
  h <- horizons(i)
  idn <- idname(i)
  this.id <- h[[idn]][1]

  idx <- grep('^A|^C', h$name)

  res <- data.frame(
    id = this.id,
    top = h$top[idx],
    bottom = h$bottom[idx]
  )
  names(res)[1] <- idn

  return(res)
}

# combined brackets
b1 <- profileApply(sp1, combinedBracket, frameify = TRUE)

# individual brackets
b2 <- profileApply(sp1, individualBrackets, frameify = TRUE)

# plot in reverse order
plotSPC(sp1, plot.order = rev(1:length(sp1)), width = 0.25)

# note that plotting order is derived from the call to `plotSPC(sp1)`
addBracket(b1, col='red', offset = -0.35)

# plot in reverse order
plotSPC(sp1, plot.order = rev(1:length(sp1)), width = 0.25)

```

```
# note that plotting order is derived from the call to `plotSPC(sp1)`  
addBracket(b2, col='red', offset = -0.35)
```

---

addDiagnosticBracket *Annotate Diagnostic Features*

---

## Description

Annotate diagnostic features within a sketch of soil profiles.

## Usage

```
addDiagnosticBracket(  
  s,  
  kind,  
  feature = "featkind",  
  top = "featdept",  
  bottom = "featdepb",  
  ...  
)
```

## Arguments

s	SoilProfileCollection object
kind	filter applied to feature column of diagnostic horizons registered within s
feature	column name containing feature kind
top	column name containing feature top depth
bottom	column name containing feature top depth
...	additional arguments passed to addBracket

## Details

Additional examples can be found in [this tutorial](#).

## Note

This is a low-level plotting function: you must first plot a SoilProfileCollection object before using this function.

---

addVolumeFraction      *Symbolize Volume Fraction on a Soil Profile Collection Plot*

---

### Description

Symbolize volume fraction on an existing soil profile collection plot.

### Usage

```
addVolumeFraction(  
  x,  
  colname,  
  res = 10,  
  cex.min = 0.1,  
  cex.max = 0.5,  
  pch = 1,  
  col = "black"  
)
```

### Arguments

x	a SoilProfileCollection object
colname	character vector of length 1, naming the column containing volume fraction data (horizon-level attribute)
res	integer, resolution of the grid used to symbolize volume fraction
cex.min	minimum symbol size
cex.max	maximum symbol size
pch	integer, plotting character code
col	symbol color, either a single color or as many colors as there are horizons in x

### Details

This function can only be called after plotting a SoilProfileCollection object. Details associated with a call to plotSPC are automatically accounted for within this function: e.g. plot.order, width, etc..

### Author(s)

D.E. Beaudette

### See Also

[plotSPC](#)

---

aggregateColor	<i>Summarize Soil Colors</i>
----------------	------------------------------

---

### Description

Summarize soil color data, weighted by occurrence and horizon thickness.

### Usage

```
aggregateColor(
  x,
  groups = "genhz",
  col = "soil_color",
  colorSpace = "CIE2000",
  k = NULL,
  profile_wt = NULL,
  mixingMethod = c("estimate", "exact")
)
```

### Arguments

<code>x</code>	a <code>SoilProfileCollection</code> object
<code>groups</code>	the name of a horizon or site attribute used to group horizons, see examples
<code>col</code>	the name of a horizon-level attribute with soil color specified in hexadecimal (i.e. "#rrggbb")
<code>colorSpace</code>	(now deprecated, removed in aqp 2.1) 'CIE2000' used for all cases
<code>k</code>	single integer specifying the number of colors discretized via PAM ( <a href="#">cluster::pam()</a> ), see details
<code>profile_wt</code>	the name of a site-level attribute used to modify weighting, e.g. area
<code>mixingMethod</code>	method used to estimate "aggregate" soil colors, see <a href="#">mixMunsell()</a>

### Details

Weights are computed by:  $w_i = \sqrt{\text{sum}(\text{thickness}_i)} * n_i$  where  $w_i$  is the weight associated with color  $i$ ,  $\text{thickness}_i$  is the total thickness of all horizons associated with the color  $i$ , and  $n_i$  is the number of horizons associated with color  $i$ . Weights are computed within groups specified by `groups`.

### Value

A list with the following components:

<code>scaled.data</code>	a list of colors and associated weights, one item for each generalized horizon label with at least one color specified in the source data
<code>aggregate.data</code>	a <code>data.frame</code> of weighted-mean colors, one row for each generalized horizon label with at least one color specified in the source data

## End(Not run)

```

---

aggregateSoilDepth      *Probabilistic Estimation of Soil Depth within Groups*

---

## Description

Estimate the most-likely depth to contact within a collection of soil profiles. Consider `getSoilDepthClass` followed by group-wise percentile estimation as a faster alternative.

## Usage

```

aggregateSoilDepth(
  x,
  groups,
  crit.prob = 0.9,
  name = hzdesgname(x),
  p = "Cr|R|Cd",
  ...
)

```

## Arguments

<code>x</code>	a <code>SoilProfileCollection</code> object
<code>groups</code>	the name of a site-level attribute that defines groups of profiles within a collection
<code>crit.prob</code>	probability cutoff used to determine where the most likely depth to contact will be, e.g. 0.9 translates to 90% of profiles are shallower than this depth

name	horizon-level attribute where horizon designation is stored, defaults to hzdesgname(x)
p	a REGEX pattern that matches non-soil genetic horizons
...	additional arguments to slab

### Details

This function computes a probability-based estimate of soil depth by group. If no grouping variable exists, a dummy value can be used to compute a single estimate. The `crit.prob` argument sets the critical probability (e.g. 0.9) at which soil depth within a group of profiles is determined. For example, a `crit.prob` of 0.95 might result in an estimated soil depth (e.g. 120cm) where 95% of the profiles (by group) had depths that were less than or equal to 120cm.

### Value

A `data.frame` is returned, with as many rows as there are unique group labels, as specified in `groups`.

### Author(s)

D.E. Beaudette

### See Also

[estimateSoilDepth\(\)](#) [slab\(\)](#)

### Examples

```
data(sp1)
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

# set horizon designation in SPC
hzdesgname(sp1) <- 'name'

aggregateSoilDepth(sp1, 'group', crit.prob = 0.9)
```

---

alignTransect

*Calculate Relative Positions from Transect Data*

---

### Description

This function is used to support relative positioning of soil profiles by `plotSPC`, based on transect or gradient values typically associated with a site level attribute (e.g. elevation). Gradient values specified in `x` are translated to the range used by `plotSPC` (usually 1, `length(SPC)`) specified in `x.min` and `x.max`.

**Usage**

```
alignTransect(x, x.min, x.max, fix = TRUE, ...)
```

**Arguments**

<code>x</code>	numeric vector, describing values along a transect: distance, elevation, climatic variables, etc.. Typically sourced from the site level attributes of a <code>SoilProfileCollection</code> object. Order is not important.
<code>x.min</code>	numeric, lower boundary to relative position scale
<code>x.max</code>	numeric, upper boundary to relative position scale
<code>fix</code>	logical, attempt fixing overlapping positions with <code>fixOverlap</code>
<code>...</code>	additional arguments to <code>fixOverlap</code>

**Details**

See the [Pair-Wise Distances by Generalized Horizon Labels](#) tutorial for additional examples.

**Value**

list containing:

- `grad`: values of `x` in ascending order
- `order`: ordering vector of `x`
- `relative.pos`: elements of `x` translated to the new relative scale defined by `x.min` and `x.max`

**Examples**

```
data("sierraTransect")

# split transects
g <- subset(sierraTransect, transect == 'Granite')
a <- subset(sierraTransect, transect == 'Andesite')

g.p <- alignTransect(g$elev, x.min = 1, x.max = length(g), fix = FALSE)
a.p <- alignTransect(a$elev, x.min = 1, x.max = length(a), fix = FALSE)

op <- par(mar=c(2,0,0,2), mfrow=c(2,1))

plotSPC(g, width=0.25, name.style='center-center',
        cex.names=0.75,
        relative.pos = g.p$relative.pos, plot.order = g.p$order)

axis(1, at = g.p$relative.pos, labels = g.p$grad, line = -1.5)

plotSPC(a, width=0.25, name.style='center-center',
        cex.names=0.75,
        relative.pos = a.p$relative.pos, plot.order = a.p$order)
```

```
axis(1, at = a.p$relative.pos, labels = a.p$grad, line = -1.5)
```

```
par(op)
```

---

 allocate

---

*Allocate soil properties within various classification systems.*

---

### Description

Generic function to allocate soil properties to different classification schemes.

### Usage

```
allocate(
  ...,
  to = c("FAO Salt Severity", "FAO Black Soil", "ST Diagnostic Features"),
  droplevels = FALSE
)
```

### Arguments

...	arguments to specific allocation functions, see details and examples
to	character specifying the classification scheme: FAO Salt Severity, FAO Black Soil (see details for the required ...)
droplevels	logical indicating whether to drop unused levels in factors. This is useful when the results have a large number of unused classes, which can waste space in tables and figures.

### Details

This function is intended to allocate a set of soil properties to an established soil classification scheme, such as Salt Severity or Black Soil. Allocation is semantically different from classification. While classification is the 'act' of developing a grouping scheme, allocation is the assignment or identification of measurements to a established class (Powell, 2008).

#### Usage Details:

Each classification scheme (to argument) uses a different set of arguments.

- FAO Salt Severity
  - **EC**: electrical conductivity column name, dS/m
  - **pH**: pH column name, saturated paste extract
  - **ESP**: exchangeable sodium percentage column name, percent
- FAO Black Soils
  - **object**: a data.frame or SoilProfileCollection
  - **pedonid**: pedon ID column name, required when object is a data.frame

- **hztop**: horizon top depth column name, required when object is a `data.frame`
- **hzbot**: horizon bottom depth column name, required when object is a `data.frame`
- **OC**: organic carbon column name, percent
- **m\_chroma**: moist Munsell chroma column name
- **m\_value**: moist Munsell value column name
- **d\_value**: dry Munsell value column name
- **CEC**: cation exchange capacity column name (NH<sub>4</sub>OAc at pH 7), units of cmol(+)/kg soil
- **BS**: base saturation column name (NH<sub>4</sub>OAc at pH 7), percent
- **tropical**: logical, data are associated with "tropical soils"
- ST Diagnostic Features
  - **object**: a `data.frame` or `SoilProfileCollection`
  - **pedonid**: pedon ID column name, required when object is a `data.frame`
  - **hzname**: horizon name column, required when object is a `data.frame`
  - **hztop**: horizon top depth column name, required when object is a `data.frame`
  - **hzbot**: horizon bottom depth column name, required when object is a `data.frame`
  - **texcl**: soil texture class (USDA) column name
  - **rupresblkcem**: rupture resistance column name
  - **m\_value**: moist Munsell value column name
  - **m\_chroma**: moist Munsell chroma column name
  - **d\_value**: dry Munsell value column name
  - **BS**: base saturation column name (method ??), percent
  - **OC**: organic carbon column name, percent
  - **n\_value**: ??
  - **featkind**: ??

### Value

A vector or `data.frame` object.

### Note

The results returned by `allocate(to = "ST Diagnostic Features")` currently return a limited set of diagnostic features that are easily defined. Also, the logic implemented for some features does not include all the criteria defined in the Keys to Soil Taxonomy.

```

---

aqp\_df\_class,SoilProfileCollection-method

*Get aqp\_df\_class entry from metadata or return a safe value.*

---

**Description**

This is an accessor and replacement method for the `aqp_df_class` entry in the metadata slot. This entry is used internally by methods that interact with `data.frame` objects and slots to ensure that the same class used to promote to the `SoilProfileCollection` initially is used throughout the process.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
aqp_df_class(object)

## S4 replacement method for signature 'SoilProfileCollection'
aqp_df_class(object) <- value
```

**Arguments**

<code>object</code>	a <code>SoilProfileCollection</code>
<code>value</code>	"data.frame", "data.table" or "tbl_df"

---

```
argillic.clay.increase.depth
```

*Return upper boundary of argillic horizon*

---

**Description**

Returns the top depth of the argillic horizon as a numeric vector.

**Usage**

```
argillic.clay.increase.depth(p, clay.attr = "clay")
```

**Arguments**

<code>p</code>	A single-profile <code>SoilProfileCollection</code> object.
<code>clay.attr</code>	OPTIONAL: horizon attribute name referring to clay content. default: <code>clay</code>

**Details**

Uses `crit.clay.argillic` to determine threshold clay increase, and `get.increase.matrix` to determine where increase is met within a vertical distance of 30 cm.

**Value**

A numeric vector containing top depth of argillic horizon, if present, or NA.

**Author(s)**

Andrew Gene Brown

**See Also**

getArgillicBounds, get.increase.matrix, crit.clay.argillic

**Examples**

```
data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1[1]
attr <- 'prop' # clay contents
foo <- argillic.clay.increase.depth(p, clay.attr = attr)
foo
```

---

as

*Coerce SoilProfileCollection with as()*

---

**Description**

SoilProfileCollections can be coerced to other R object types using `as(spc, 'type')`.

Possible endpoints include: `list`, `data.frame`, `SpatialPointsDataFrame` and `SpatialPoints`.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
as.data.frame(x)
```

**Arguments**

x                    a SoilProfileCollection

**Value**

list  
data.frame  
tbl\_df  
data.table  
SpatialPointsDataFrame  
sf  
SpatialPoints

**Examples**

```

# load example data stored as SoilProfileCollection
data(sp5)

# sp5
str(sp5)

# list output
str(as(sp5, 'list'))

# data.frame output
str(as(sp5, 'data.frame'))

# Spatial Objects
# make some random coordinate data for each profile
sp5$x <- sp5$y <- rnorm(length(sp5))
initSpatial(sp5, crs = "OGC:CRS84") <- ~ x + y

# SpatialPointsDataFrame output
str(as(sp5, 'SpatialPointsDataFrame'))

# SpatialPoints output
str(as(sp5, 'SpatialPoints'))

```

---

barron.torrent.redness.LAB

*Barron & Torrent (1986) Redness Index in LAB color space*

---

**Description**

Calculate Redness Index after Barron & Torrent (1986) "Use of the Kubelka—Munk Theory to Study the Influence of Iron Oxides on Soil Colour" using Munsell colors converted to LAB. DOI: 10.1111/j.1365-2389.1986.tb00382.x. Accepts vectorized inputs for hue, value and chroma, produces vector output.

**Usage**

```
barron.torrent.redness.LAB(hue, value, chroma)
```

**Arguments**

hue	A character vector containing Munsell hues (e.g. "7.5YR")
value	A numeric vector containing Munsell values
chroma	A numeric vector containing Munsell chromas

**Value**

A numeric vector of horizon redness index (higher values = redder).

**Author(s)**

Andrew G. Brown

**References**

Barron, V. and Torrent, J. (1986), Use of the Kubelka—Munk theory to study the influence of iron oxides on soil colour. *Journal of Soil Science*, 37: 499-510. doi:10.1111/j.1365-2389.1986.tb00382.x

---

bootstrapSoilTexture *Bootstrap Soil Texture Data*

---

**Description**

Simulate realistic sand/silt/clay values (a composition) using multivariate Normal distribution or Dirichlet distribution. Simulations from the multivariate Normal distribution are based on the compositional mean and variance-covariance matrix. Simulations from the Dirichlet distribution are based on maximum likelihood estimation of alpha parameters.

**Usage**

```
bootstrapSoilTexture(ssc, method = c("dirichlet", "normal"), n = 100)
```

**Arguments**

ssc	a data.frame object with 3 columns: 'sand', 'silt', 'clay' and at least three rows of data within the range of 0-100 (percent). NA are automatically removed, but care should be taken to ensure that the sand/silt/clay values add to 100 percent. Simulations are based on these examples.
method	type of simulation: 'dirichlet' or 'normal'. See details.
n	number of simulated compositions. See details.

**Details**

Simulations from the multivariate normal distribution will more closely track the marginal distributions of sand, silt, and clay—possibly a better fit for "squished" compositions (TODO elaborate). However, these simulations can result in extreme (unlikely) estimates.

Simulations from the Dirichlet distribution will usually be a better fit (fewer extreme estimates) but require a fairly large number of records in ssc ( $n \geq 30$ ?) for a reliable fit.

Additional examples will be added to [this tutorial](#).

**Value**

a list containing:

- samples - data.frame of simulated sand, silt, clay values
- mean - compositional mean
- var - compositional variance-covariance matrix
- D.alpha - (fitted) alpha parameters of the Dirichlet distribution, NULL when method = 'normal'

)
}

```

---

brierScore

*Multinomial Brier Score*

---

### Description

Compute a multinomial Brier score from predicted class probabilities and observed class label. Lower values are associated with a more accurate classifier.

### Usage

```
brierScore(x, classLabels, actual = "actual")
```

### Arguments

x	data.frame of class probabilities (numeric) and observed class label (character), see examples
classLabels	vector of predicted class labels (probabilities), corresponding to column names in x
actual	name of column containing the observed class, should be character vector not factor

**Value**

a single Brier score, representative of data in x

**Author(s)**

D.E. Beaudette

**References**

  c = c(0.05, 0.10, 0.15),
  actual = c('b', 'b', 'b'),
  stringsAsFactors = TRUE
)

# relatively low value = accurate
brierScore(x = d.good, classLabels = c('a', 'b', 'c'), actual = 'actual')

# high values = not accurate
brierScore(x = d.bad, classLabels = c('a', 'b', 'c'), actual = 'actual')

# message related to conversion of factor -> character
```

```
brierScore(x = d.factors, classLabels = c('a', 'b', 'c'), actual = 'actual')
```

---

buntley.westin.index *Buntley-Westin (1965) Index*

---

### **Description**

Calculate "Color Development Equivalent" by the method of Buntley & Westin (1965) "A Comparative Study of Developmental Color in a Chestnut-Chernozem-Brunizem Soil Climosequence" DOI: 10.2136/sssaj1965.03615995002900050029x. Originally developed for Mollisols, the Buntley-Westin index has been used as a tool to separate soils based on depth to particular colors.

### **Usage**

```
buntley.westin.index(hue, chroma)
```

### **Arguments**

hue	A character vector containing Munsell hues (e.g. "7.5YR")
chroma	A numeric vector containing Munsell chromas

### **Value**

A numeric vector reflecting horizon color development.

### **Author(s)**

Andrew G. Brown

### **References**

c,SoilProfileCollection-method

*Combine SoilProfileCollection objects*

---

### Description

Combine SoilProfileCollection objects or lists of SoilProfileCollection objects. This method provides ... expansion for the pbindlist method.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
c(x, ...)

## S4 method for signature 'SoilProfileCollection'
combine(...)

## S4 method for signature 'list'
combine(...)
```

### Arguments

x	A SoilProfileCollection
...	SoilProfileCollection objects

### Value

A SoilProfileCollection

### Examples

```
# example data
spc1 <- random_profile(1, SPC = TRUE)
spc2 <- random_profile(2, SPC = TRUE)
spc3 <- random_profile('A', SPC = TRUE)

# combine into a single SPC, ... interface
spc <- combine(spc1, spc2, spc3)

# combine into a single SPC, list interface
spc <- combine(list(spc1, spc2, spc3))

# input are combined into a single SPC
spc <- c(spc1, spc2, spc3)

# result is a list when a mixture of objects are provided
spc <- c(spc1, bar=spc2, baz="foo")
```

ca630

*Soil Data from the Central Sierra Nevada Region of California***Description**

Site and laboratory data from soils sampled in the central Sierra Nevada Region of California.

**Usage**

```
data(ca630)
```

**Format**

List containing:

\$site : A data frame containing site information.

**user\_site\_id** national user site id

**mlra** the MLRA

**county** the county

**ssa** soil survey area

**lon** longitude, WGS84

**lat** latitude, WGS84

**pedon\_key** national soil profile id

**user\_pedon\_id** local soil profile id

**cntrl\_depth\_to\_top** control section top depth (cm)

**cntrl\_depth\_to\_bot** control section bottom depth (cm)

**sampled\_taxon\_name** soil series name

\$lab : A data frame containing horizon information.

**pedon\_key** national soil profile id

**layer\_key** national horizon id

**layer\_sequence** horizon sequence number

**hzn\_top** horizon top (cm)

**hzn\_bot** horizon bottom (cm)

**hzn\_desgn** horizon name

**texture\_description** USDA soil texture

**nh4\_sum\_bases** sum of bases extracted by ammonium acetate (pH 7)

**ex\_acid** exchangeable acidity [method ?]

**CEC8.2** cation exchange capacity by sum of cations method (pH 8.2)

**CEC7** cation exchange capacity by ammonium acetate (pH 7)

**bs\_8.2** base saturation by sum of cations method (pH 8.2)

**bs\_7** base saturation by ammonium acetate (pH 7)

## Details

These data were extracted from the NSSL database. ca630 is a list composed of site and lab data, each stored as data.frame objects. These data are modeled by a 1:many (site:lab) relation, with the pedon\_id acting as the primary key in the site table and as the foreign key in the lab table.

## Note

These data are out of date. Pending some new data + documentation. Use with caution

---

checkHzDepthLogic	<i>Check a SoilProfileCollection object for errors in horizon depths.</i>
-------------------	---

---

### Description

This function inspects a `SoilProfileCollection` object, looking for four common errors in horizon depths:

1. bottom depth shallower than top depth
2. equal top and bottom depth
3. missing top or bottom depth (e.g. NA)
4. gap or overlap between adjacent horizons (only if `byhz = FALSE`)

### Usage

```

checkHzDepthLogic(
  x,
  hzdepths = NULL,
  idname = NULL,
  fast = FALSE,
  byhz = FALSE
)

```

### Arguments

<code>x</code>	SoilProfileCollection or data.frame object to check
<code>hzdepths</code>	character vector, describing top and bottom depths in a SoilProfileCollection or data.frame. <code>horizonDepths(x)</code> is used when <code>x</code> is a SoilProfileCollection.
<code>idname</code>	character, describing the column containing profile IDs in a SoilProfileCollection or data.frame. <code>idname(x)</code> is used when <code>x</code> is a SoilProfileCollection.
<code>fast</code>	logical, When TRUE, details about specific test results are not needed, the operation can allocate less memory and run approximately 5x faster.
<code>byhz</code>	logical, apply logic tests to profiles (FALSE) or individual horizons (TRUE)?

**Value**

A data.frame containing profile IDs, validity boolean (`valid`) and test results if `fast = FALSE`. The data.frame will have as many rows as profiles in `x` (`length(x)`).

- `id` : Profile IDs, named according to `idname(x)`
- `valid` : boolean, profile passes all of the following tests
- `depthLogic` : boolean, errors related to depth logic
- `sameDepth` : boolean, errors related to same top/bottom depths
- `missingDepth` : boolean, NA in top / bottom depths
- `overlapOrGap` : boolean, gaps or overlap in adjacent horizons (NA when `byhz = TRUE`)

**Author(s)**

D.E. Beaudette, A.G. Brown, S.M. Roecker

**Examples**

```
## sample data

data(sp3)
depths(sp3) <- id ~ top + bottom

# these data should be clean
res <- checkHzDepthLogic(sp3)

head(res)

# less memory if only concerned about net validity
res <- checkHzDepthLogic(sp3, fast = TRUE)

head(res)
```

---

checkSPC

*Test for a valid SoilProfileCollection*

---

**Description**

Test for a valid SoilProfileCollection

**Usage**

```
checkSPC(x)
```

**Arguments**

`x` a SoilProfileCollection object

**Details**

Test for valid SoilProfileCollection by checking for slots defined in the class prototype. Likely only used between major versions of aqp where internal structure of SoilProfileCollection has changed. Use checkHzDepthLogic to check for common errors in horizon depths.

**Value**

TRUE or FALSE. Consider using rebuildSPC() if FALSE.

**Author(s)**

D.E. Beaudette

**See Also**

---

 col2Munsell

---

*Convert colors into Munsell Notation*

---

**Description**

Lookup the n closest Munsell chips from the munsell lookup table from various color notations. This function replaces rgb2munsell().

**Usage**

```
col2Munsell(col, space = c("sRGB", "CIELAB"), nClosest = 1)
```

**Arguments**

col	character vector of colors, data.frame or matrix of color coordinates in sRGB or CIELAB color space
space	character, one of sRGB or CIELAB, defines the input color system
nClosest	integer, number of closest Munsell colors to return (valid range is 1-20)

**Value**

an (NA-padded) data.frame containing hue, value, chroma, and CIE delta-E 2000 color contrast metric between source and nearest matching color(s).

**Note**

This function is fully vectorized and will pad output with NA-records when NA are present in color.

**Author(s)**

D.E. Beaudette

```
# vector of named R colors
col2Munsell(c('red', 'green', 'blue'))

# sRGB matrix in the range of 0-255
col2Munsell(cbind(255, 0, 0))

# sRGB matrix in the range of 0-1
col2Munsell(cbind(1, 0, 0))

# 10YR 5/6 in CIELAB
col2Munsell(
  cbind(51.4337, 9.917916, 38.6889),
  space = 'CIELAB'
)

# 2.5YR 6/8 in hex notation
col2Munsell("#D18158FF")

# 7.5YR 8/1 in sRGB {0, 1}
col2Munsell(
  cbind(0.8240707, 0.7856834, 0.7541048)
)

# 7.5YR 8/1 in sRGB {0, 255}
col2Munsell(
  cbind(0.8240707, 0.7856834, 0.7541048) * 255
)

# multiple colors in CIELAB
col2Munsell(
  parseMunsell(c('10BG 6/6', '2.5YR 4/6'), returnLAB = TRUE),
  space = 'CIELAB'
)

# data.frame input
col2Munsell(
  data.frame(r = 1, g = 0, b = 0),
  space = 'sRGB'
)
```

```

# keep examples from using more than 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

# Munsell notation to sRGB triplets {0, 1}
color <- munsell2rgb(
  the_hue = c('10YR', '2.5YR', '5YR'),
  the_value = c(3, 5, 2.5),
  the_chroma = c(5, 6, 2),
  return_triplets = TRUE
)

# result is a data.frame of sRGB {0, 1}
color

# back-transform sRGB -> closest Munsell color
# sigma is the dE00 color contrast metric
col2Munsell(color, space = 'sRGB')

```

---

colorChart	<i>Visualize soil colors in Munsell notation according to within-group frequency.</i>
------------	---

---

## Description

Visualize soil colors in Munsell notation according to within-group frequency.

## Usage

```

colorChart(
  m,
  g = factor("All"),
  size = TRUE,
  annotate = FALSE,
  chip.cex = 3,
  chip.cex.min = 0.1,
  chip.cex.max = 1.5,
  chip.border.col = "black",
  annotate.cex = chip.cex * 0.25,
  annotate.type = c("count", "percentage"),
  threshold = NULL
)

```

## Arguments

m	character vector of color in Munsell notation ('10YR 4/6')
g	factor describing group membership, typically a generalization of horizon designation, default value will generate a fake grouping that covers all of the colors in m

size	logical, encode group-wise frequency with chip size
annotate	logical, annotate color chip frequency
chip.cex	scaling factor applied to each color chip
chip.cex.min	lower limit for color chip frequency depiction
chip.cex.max	lower limit for color chip frequency depiction
chip.border.col	color for chip borders (outline)
annotate.cex	scaling factor for chip frequency annotation
annotate.type	character, within-group count or percentage
threshold	numeric within 0-1, color chips with proportion < threshold are removed

**Value**

a trellis object

**Examples**

```
# required for latticeExtra:useOuterStrips
if(!requireNamespace('latticeExtra')) {

  # two hue pages
  ric <- expand.grid(
    hue = c('5YR', '7.5YR'),
    value = 2:8,
    chroma = 2:8
  )

  # combine hue, value, chroma into standard Munsell notation
  ric <- sprintf("%s %s/%s", ric$hue, ric$value, ric$chroma)

  # note that chip frequency-based size is disabled
  # because all chips have equal frequency
  colorChart(ric, chip.cex = 4, size = TRUE)

  # annotation of frequency
  colorChart(ric, chip.cex = 4, annotate = TRUE)

  # bootstrap to larger size
  ric.big <- sample(ric, size = 100, replace = TRUE)

  # frequency can be encoded in size
  colorChart(ric.big, chip.cex = 3)
  colorChart(ric.big, chip.cex = 5, annotate = TRUE)

  # constant size
  colorChart(ric.big, chip.cex = 3, size = FALSE)
  colorChart(ric.big, chip.cex = 3, size = FALSE, chip.border.col = 'NA')
```

```

# simulate colors based dE00 thresholding
p <- list(
  list(m = '10YR 4/4', thresh = 10, hues = c('10YR', '7.5YR'))
)

# perform 500 simulations
s <- simulateColor(method = 'dE00', n = 500, parameters = p)

# result is a list, use the first element
colorChart(s[[1]], chip.cex = 4)

# increase the possible range of color chip sizes
colorChart(s[[1]], chip.cex = 4, chip.cex.min = 0.01, chip.cex.max = 2)

# slightly funky support for neutral hues
N <- sprintf('N %s/', 2:8)
cols <- c(rep(N, times = 5), ric.big)

# note special panel used to show neutral hues
colorChart(cols, size = FALSE, annotate = TRUE)

# filter proportions below given threshold
colorChart(cols, size = FALSE, annotate = TRUE, threshold = 0.01,
chip.cex = 4, annotate.type = 'percentage')
}

```

---

colorContrast

*Metrics of Contrast Suitable for Comparing Soil Colors*

---

### Description

Pair-wise comparisons of Munsell color specifications, based on the NCSS color contrast classes (Soil Survey Technical Note 2) and CIE delta-E 2000 metric.

### Usage

```
colorContrast(m1, m2)
```

### Arguments

m1	vector of Munsell colors ('10YR 3/3')
m2	vector of Munsell colors ('10YR 3/6')

## Details

This function is fully vectorized but expects input to be of the same length. Use `expand.grid()` to generate suitable input from 1:many or many:1 type comparisons. See [this tutorial](#) for an expanded discussion and more examples. Neutral colors are not mentioned in SSTN2: in this function any comparison to a neutral color (e.g. 'N 3/') are assigned a delta-hue of 1. Since SSTN2 expects hues to be counted clock wise from 5R, it possible to get very large delta-hue values for otherwise adjacent colors: '5R' vs. '2.5R'. This will be addressed in an update to the standards.

The most meaningful representation of color contrast is the CIE2000 (dE00) metric.

## Value

data.frame with the following columns:

- m1: Munsell color 1
- m2: Munsell color 2
- dH: delta-hue, as computed by `huePosition`
- dV: delta-value, absolute value of difference in Munsell value (m1 vs. m2)
- dc: delta-chroma, absolute value of difference in Munsell chroma (m1 vs. m2)
- dE00: delta-E00, e.g. the [CIE delta-E as refined in 2000](#)
- cc: soil color contrast class, as specified in Soil Survey Technical Note 2.

## Note

delta-E00 is computed by the [farver](#) package.

## Author(s)

D.E. Beaudette

## References

## Examples

```
# keep examples from using more than 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

# two sets of colors to compare
m1 <- c('10YR 6/3', '7.5YR 3/3', '10YR 2/2', '7.5YR 3/4')
m2 <- c('5YR 3/4', '7.5YR 4/4', '2.5YR 2/2', '7.5YR 6/3')

# contrast metrics
```

```

colorContrast(m1, m2)

# adjacent chips
colorContrast('10YR 3/3', '10YR 3/4')
colorContrast('10YR 3/3', '7.5YR 3/3')

# highly contrasting colors
# http://colour.granjow.net/fabercastell-polychromos.html
colorContrastPlot('10B 4/13', '10YR 10/15',
  labels = c('helioblue-reddish', 'light cadmium yellow')
)

## Note: neutral hues aren't defined in TN2
# approximation / extension of the concept
colorContrast(m1 = 'N 3/', m2 = 'N 6/')

#
colorContrast(m1 = '10YR 3/3', m2 = 'N 3/')

m1 <- c('10YR 6/3', '7.5YR 3/3', '10YR 2/2', 'N 3/')
m2 <- c('5YR 3/4', '7.5YR 4/4', '2.5YR 2/2', '7.5YR 6/3')
colorContrast(m1, m2)

```

---

colorContrastPlot

*Color Contrast Plot*

---

## Description

A simple display of two sets of colors, NCSS color contrast class and CIE delta-E00.

## Usage

```

colorContrastPlot(
  m1,
  m2,
  col.cex = 1,
  col.font = 2,
  d.cex = 1,
  cc.font = 3,
  dE00.font = 1,
  labels = c("m1", "m2"),
  label.cex = 1,
  label.font = 1,
  printMetrics = TRUE,
  ...
)

```

**Arguments**

m1	first set of Munsell colors for comparison (e.g. '5YR 3/2')
m2	second set of Munsell colors for comparison
col.cex	scaling factor for color labels
col.font	font for color labels
d.cex	contrast for contrast metric labels
cc.font	font for contrast class
dE00.font	font for delta-E00
labels	labels for compared colors, vector length 2
label.cex	scaling factor for labels
label.font	font for labels
printMetrics	logical, print metrics between color swatches
...	further arguments to <code>colorspace::swatchplot</code>

**Note**

This function requires the `farver` package for calculation of CIE delta-E00.

colorContrast(m1, m2)

# graphical display
colorContrastPlot(m1, m2)
```

---

colorQuantiles	<i>Soil Color Range via Quantiles</i>
----------------	---------------------------------------

---

**Description**

Estimate central tendency and spread of soil color using marginal quantiles and L1 median of CIELAB coordinates.

**Usage**

```
colorQuantiles(soilColors, p = c(0.05, 0.5, 0.95))
```

**Arguments**

soilColors	vector of R colors (sRGB colorspace)
p	marginal quantiles of interest

**Details**

Colors are converted from sRGB to CIELAB (D65 illuminant), marginal quantiles of (L,A,B) coordinates are estimated, and L1 median (L,A,B) is estimates. The closest Munsell chips (via Munsell/CIELAB lookup table provided by `munsell`) and R colors are determined by locating chips closest to the marginal quantiles and L1 median.

The results can be conveniently inspected using `plotColorQuantiles()`.

**Value**

A List containing the following elements:

- `marginal`: data.frame containing marginal quantiles in CIELAB (D65), closest Munsell chips, and dE00
- `L1`: L1 median CIELAB (D65) values, closest Munsell chip, and dE00

**Author(s)**

D.E. Beaudette

**Examples**

```
## Not run:  
# example data, see manual page for details  
data(sp5)  
  
# slice top 25 cm  
# 24-25cm is the last slice  
s <- dice(sp5, 0:24 ~ .)
```

```

# check some of the data
par(mar=c(0,0,0,0))
plotSPC(sample(s, 25), divide.hz = FALSE, name = '', print.id = FALSE, width = 0.5)

# colors
previewColors(unique(s$soil_color))

# compute marginal quantiles and L1 median
cq <- colorQuantiles(s$soil_color)

# simple graphical display of results
plotColorQuantiles(cq)

## End(Not run)

```

---

compareSites

*Compare Site Level Attributes of a SoilProfileCollection*

---

### Description

Compare site level attributes of a `SoilProfileCollection` object, returning a distance matrix conformal with the output from `NCSP()`. Values are within the range of 0-1.

### Usage

```
compareSites(x, vars, weights = rep(1, times = length(vars)), ...)
```

### Arguments

<code>x</code>	SoilProfileCollection object
<code>vars</code>	character vector listing one or more site level attributes of <code>x</code>
<code>weights</code>	numeric vector, same length as <code>vars</code> , variable weighting
<code>...</code>	additional arguments to <code>cluster::daisy()</code>

### Details

This function is typically used in conjunction with the output from `NCSP()`.

### Value

dissimilarity / dist class object containing pair-wise distances, row/column names derived from `profile_id(x)`

### See Also

`NCSP()` `cluster::daisy()`

---

compositeSPC	<i>Return a list representation of site and horizon level data</i>
--------------	--

---

**Description**

compositeSPC() is a convenience function that returns a named list representation of the columns from the @site and @horizons slots.

**Usage**

```
compositeSPC(object)
```

**Arguments**

object            A SoilProfileCollection

**Value**

A list.

**Author(s)**

Andrew G. Brown.

---

confusionIndex	<i>Confusion Index</i>
----------------	------------------------

---

**Description**

Calculate the confusion index of Burrough et al., 1997.

**Usage**

```
confusionIndex(x)
```

**Arguments**

x                    vector of probabilities (0,1), should not contain NA

**Value**

A single numeric value.

**Author(s)**

D.E. Beaudette

## References

Burrough, P.A., P.F.M. van Gaans, and R. Hootsmans. 1997. "Continuous Classification in Soil Survey: Spatial Correlation, Confusion and Boundaries." *Geoderma* 77: 115-35. doi:10.1016/S0016-7061(97)00018-9.

## Examples

```
# a very simple example
p <- c(0.25, 0.25, 0.4, 0.05, 0.05)
confusionIndex(p)

# for comparison
shannonEntropy(p)
```

---

contrastChart

*Color Contrast Chart*

---

## Description

Compare one or more pages from a simulated Munsell book of soil colors to a reference color.

## Usage

```
contrastChart(
  m,
  hues,
  ccAbbreviate = 1,
  style = "hue",
  gridLines = FALSE,
  de00.cex = 0.6,
  cc.cex = 0.6,
  thresh = NULL,
  returnData = FALSE
)
```

## Arguments

m	Munsell representation of a single color for comparison e.g. '10YR 4/3'
hues	vector of one or more Munsell hue pages to display
ccAbbreviate	length of abbreviated contrast classes, use 0 to suppress labels
style	'hue' or 'CC', see details
gridLines	logical, add grid lines to the color contrast chart
de00.cex	character scaling applied to dE00 annotation
cc.cex	character scaling applied to contrast class annotation
thresh	threshold (<) applied to pair-wise comparisons and resulting color chips
returnData	logical, return lattice figure + data used to generate the figure

## Details

A simulated Munsell color book page or pages are used to demonstrate color contrast between all chips and the reference color *m* (highlighted in red). NCSS color contrast class and CIE delta-E00 values are printed below all other color chips. Munsell color chips for chroma 5 and 7 are omitted, but axis labels are retained as a reminder of this fact.

Setting `style='hue'` emphasizes the contrast classes and CIE delta-E00 of chips adjacent to *m*. Setting `style='CC'` emphasizes adjacent chips according to respective contrast class via lattice panels.

Two-way panels are used when multiple hues are provided and `style='CC'`. The default output can be greatly enhanced via:

```
latticeExtra::useOuterStrips(..., strip = strip.custom(bg=grey(0.85)), strip.left
= strip.custom(bg=grey(0.85)))
```

## Author(s)

D.E. Beaudette

## Examples

```
# keep examples from using more than 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

# single hue page
contrastChart(m = '10YR 3/3', hues = '10YR')

# multiple hue pages
contrastChart(m = '10YR 3/3', hues = c('10YR', '2.5Y'))

# contrast class, single hue
contrastChart(m = '10YR 3/3', hues = '10YR', style='CC')

# contrast class, multiple hues
# consider latticeExtra::useOuterStrips()
contrastChart(m = '10YR 5/6', hues = c('10YR', '2.5Y'), style='CC')
```

---

contrastClass

*Soil Color Contrast*

---

## Description

Determine soil color contrast class according to methods outlined in the Soil Survey Manual. This function is typically called from `colorContrast()` which is simpler to use and provides more information.

**Usage**

```
contrastClass(v1, c1, v2, c2, dH, dV, dC, verbose = FALSE)
```

**Arguments**

v1	Munsell value of first color
c1	Munsell chroma of first color
v2	Munsell value of second color
c2	Munsell chroma of second color
dH	delta Hue
dV	delta Value
dC	delta Chroma
verbose	return a list for testing rules/cases

**Details**

This function is fully vectorized but expects all inputs have the same length.

**Value**

A vector of color contrast classes (ordered factor). A list when verbose is TRUE.

**Author(s)**

D.E. Beaudette

**References**

- Soil Survey Technical Note 2 [wayback machine URL](#)

**See Also**

[colorContrast](#)

**Examples**

```
## standard use, result is an ordered factor
# 10YR 6/3 vs 5YR 3/4
contrastClass(v1=6, c1=3, v2=3, c2=4, dH=2, dV=3, dC=1)

## verbose output, useful for testing rules/cases
# 10YR 6/3 vs 5YR 3/4
contrastClass(v1=6, c1=3, v2=3, c2=4, dH=2, dV=3, dC=1, verbose = TRUE)
```

---

correctAWC	<i>Apply rock fragment or salt correction to available water content</i>
------------	--

---

### Description

Apply rock fragment or salt correction to available water content

### Usage

```
correctAWC(
  awc,
  total_rf = numeric(length(awc)),
  gravel = NULL,
  ec = NULL,
  nullFragmentsAreZero = TRUE
)
```

### Arguments

awc	Numeric vector of available water capacities (e.g. from estimateAWC)
total_rf	Numeric vector of rock fragment volume percentage, 0 - 100
gravel	Numeric vector of gravel volume percentage, 0 - 100
ec	Numeric vector of electrical conductivity, mmhos/cm
nullFragmentsAreZero	Interpret NA in total_rf, gravel or ec as 0? Default: TRUE

### Value

A numeric vector (double) containing estimated available water capacities corrected for rock fragments and salts

### Examples

```
# medium organic matter, loam texture
base.awc <- 0.18 # estimateAWC(texcl = "1", omcl = 2, na.rm = TRUE)

# medium organic matter, loam texture w/ 23% rock fragments by volume
corrected.awc <- correctAWC(base.awc, total_rf = 23)
corrected.awc

# medium organic matter, loam texture w/ 0% frags by volume and 8 mmhos/cm salts
salty.awc <- correctAWC(base.awc, total_rf = 0, ec = 8)
salty.awc
```

---

crit.clay.argillic     *Determines threshold (minimum) clay content for argillic upper bound*

---

### Description

Given a vector or matrix of "eluvial" horizon clay contents (`\ crit.clay.argillic()`) returns a vector or matrix of minimum clay contents (thresholds) that must be met for an argillic horizon clay increase.

### Usage

```
crit.clay.argillic(eluvial_clay_content)
```

### Arguments

eluvial\_clay\_content

A numeric vector or matrix containing clay contents of potential "eluvial" horizons. May contain NA.

### Details

Uses the standard equations for clay contents less than 15 % and 40 % the definition of the argillic horizon from 12th Edition Keys to Soil Taxonomy (Soil Survey Staff, 2014).

### Value

A vector or matrix (input-dependent) containing minimum "illuvial" horizon clay contents (thresholds) to be met for argillic horizon clay increase.

### Note

This function is intended for identifying clay content threshold required for an argillic horizon. These thresholds may not apply depending on the specifics of your soil. E.g. if the upper part of argillic has been plowed (has Ap immediately over upper boundary) the clay increase requirement can be waived (Soil Survey Staff, 2014).

### Author(s)

Andrew Gene Brown

**Examples**

```
# crit.clay.argillic uses different equations for clay content
# less than 15 %, between 15 and 40 %, and >40 %

crit.clay.argillic(eluvial_clay_content=c(5, 20, 45))
```

---

denormalize	<i>Create a (redundant) horizon-level attribute from a site-level attribute</i>
-------------	---

---

**Description**

Create a (redundant) horizon-level attribute from a site-level attribute. Specify a SoilProfileCollection and a site-level attribute from that SPC (by name) to receive a vector of length equal to the number of horizons containing the site-level values. This vector is directly usable with the SoilProfileCollection horizon setter.

denormalize is the inverse operation for the formula interface that "normalizes" a horizon level variable to site level:

```
site(object) <- ~ horizonvar
```

**Usage**

```
denormalize(object, attr)
```

**Arguments**

object	A SoilProfileCollection
attr	Site-level attribute name (character string) to denormalize to horizon.

**Details**

"Denormalization" is the process of trying to improve the read performance of a database, at the expense of losing some write performance, by adding redundant copies of data or by grouping data. Sometimes it is beneficial to have site-level attributes denormalized for grouping of horizon-level data in analyses. denormalize achieves this result for SoilProfileCollections.

**Value**

A vector of values of equal length to the number of rows in the horizon table of the input SPC.

**Author(s)**

Andrew G. Brown, Dylan Beaudette

## Examples

```

data(sp1)

# create a SoilProfileCollection from horizon data
depths(sp1) <- id ~ top + bottom

# create random site-level attribute `sitevar` with a binary (0/1) outcome
sp1$sitevar <- round(runif(length(sp1)))

# use denormalize() to create a mirror of sitevar in the horizon table
# name the attribute something different (e.g. `hz.sitevar`) to
# prevent collision with the site attribute
# the attributes can have the same name but you will then need
# site() or horizons() to access explicitly
sp1$hz.sitevar <- denormalize(sp1, 'sitevar')

# compare number of profiles to number of sitevar assignments
length(sp1)
table(sp1$sitevar)

# compare number of horizons to number of horizon-level copies of sitevar `hz.'sitevar`
nrow(sp1)
table(sp1$hz.sitevar)

```

---

depthOf	<i>Get top or bottom depths of horizons matching a regular expression pattern</i>
---------	---

---

## Description

The depthOf family of functions calculate depth of occurrence of a horizon designation pattern, or any other value that can be coerced to character and matched with a regular expression.

If you need all depths of occurrence for a particular pattern, depthOf is what you are looking for. minDepthOf and maxDepthOf are wrappers around depthOf that return the minimum and maximum depth. They are all set up to handle missing values and missing "contacts" with the target pattern.

## Usage

```

depthOf(
  p,
  pattern,
  FUN = NULL,
  top = TRUE,
  hzdesgn = guessHzDesgnName(p),
  no.contact.depth = NULL,
  no.contact.assigned = NA_real_,
  na.rm = TRUE,

```

```

    simplify = TRUE
  )

maxDepthOf(
  p,
  pattern,
  top = TRUE,
  hzdesgn = guessHzDesgnName(p),
  no.contact.depth = NULL,
  no.contact.assigned = NA,
  na.rm = TRUE,
  simplify = TRUE
)

minDepthOf(
  p,
  pattern,
  top = TRUE,
  hzdesgn = guessHzDesgnName(p),
  no.contact.depth = NULL,
  no.contact.assigned = NA,
  na.rm = TRUE,
  simplify = TRUE
)

```

### Arguments

p	a SoilProfileCollection
pattern	a regular expression to match in the horizon designation column. See:hzdesgn
FUN	a function that returns a single value, and takes argument na.rm
top	should the top (TRUE) or bottom (FALSE) depth be returned for matching horizons? Default: TRUE.
hzdesgn	column name containing horizon designations. Default: guessHzDesgnName(p)
no.contact.depth	depth to assume that contact did not occur.
no.contact.assigned	depth to assign when a contact did not occur.
na.rm	logical. Remove NA? (default: TRUE)
simplify	logical. Return single profile results as vector (default: TRUE) or data.frame (FALSE)

### Value

a numeric vector containing specified depth(s) of horizons matching a pattern. If `length(p) > 1` then a *data.frame* containing profile ID, horizon ID, top or bottom depths, horizon designation and pattern.

**Author(s)**

Andrew G. Brown

**Examples**

```

# construct a fake profile
spc <- data.frame(id=1, taxsubgrp = "Lithic Haploxerepts",
  hzname = c("A","AB","Bw","BC","R"),
  hzdept = c(0, 20, 32, 42, 49),
  hzdepb = c(20, 32, 42, 49, 200),
  clay = c(19, 22, 22, 21, NA),
  texcl = c("1","1","1", "1","br"),
  d_value = c(5, 5, 5, 6, NA),
  m_value = c(2.5, 3, 3, 4, NA),
  m_chroma = c(2, 3, 4, 4, NA))

# promote to SoilProfileCollection
depths(spc) <- id ~ hzdept + hzdepb
hzdesgname(spc) <- 'hzname'
hztexclname(spc) <- 'texcl'

# multiple horizons contain B
depthOf(spc, "B")

# deepest top depth of horizon containing B
maxDepthOf(spc, "B")

# shallowest top depth
minDepthOf(spc, "B")

# deepest bottom depth
maxDepthOf(spc, "B", top = FALSE)

# deepest bottom depth above 35cm
maxDepthOf(spc, "B", top = FALSE, no.contact.depth = 35)

# assign infinity (Inf) if B horizon does not start within 10cm
minDepthOf(spc, "B", no.contact.depth = 10, no.contact.assigned = Inf)

```

---

depths

*Initialize a SoilProfileCollection from data.frame*

---

**Description**

```

depths(<data.frame>) <- <formula>: Initialize SoilProfileCollection
depths(<SoilProfileCollection>): Extract profile ID and horizon depths from SoilProfileCollection

```

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
depths(x, hzID = FALSE, ...)

## S4 replacement method for signature 'SoilProfileCollection'
depths(object) <- value

## S4 replacement method for signature 'data.frame'
depths(object) <- value
```

**Arguments**

x	A SoilProfileCollection
hzID	Include horizon ID? Usually this is calculated from the (sorted) row index unless hzidname()<- has been called. Default: FALSE
...	not used
object	An object to promote to SoilProfileCollection (inherits from data.frame)
value	A formula specifying the unique profile ID, top and bottom depth column names

**Details**

The input horizon data, and the resulting profile order, is sorted based on unique profile ID and top depth. ID columns are converted to character, depth columns are converted to integer. If NA values exist in all of the top depths, a prototype with 1 horizon per profile ID is returned, with NA in all non-essential columns. If the input object has 0 rows, a prototype with 0 horizons and 0 rows, but same column names as object, is returned.

**Value**

a data.frame containing profile ID, top depth, and bottom depth

**See Also**

horizons() idname() hzidname() horizonDepths()

**Examples**

```
# load a SoilProfileCollection
data(jacobs2000, package = "aqp")

depths(jacobs2000)
## init SoilProfileCollection objects from data.frame of horizon data

# load demo data
data(sp1)

# promote to SPC
depths(sp1) <- id ~ top + bottom
```

```
# plot
plot(sp1)

# number of profiles
length(sp1)

# number of horizons
nrow(sp1)
```

---

depthWeights	<i>Return a vector of contributing fractions over a depth interval</i>
--------------	--

---

### Description

depthWeights() calculates the contributing fraction for each pair of horizon top and bottom depths, given an upper and lower boundary.

### Usage

```
depthWeights(top, bottom, upper, lower)
```

### Arguments

top	A numeric vector of horizon top depths.
bottom	A numeric vector of horizon bottom depths.
upper	A unit length numeric vector with upper boundary.
lower	A unit length numeric vector with lower boundary.

### Value

A named list.

### Author(s)

Andrew G. Brown.

---

depth\_units,SoilProfileCollection-method  
*Get depth units from metadata*

---

**Description**

Get units of depth measurement from metadata. Default value is centimeters.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'  
depth_units(object)  
  
## S4 replacement method for signature 'SoilProfileCollection'  
depth_units(object) <- value
```

**Arguments**

object	A SoilProfileCollection
value	character, a value representing units. Default 'cm'.

**Examples**

```
data(sp5)  
  
## get depth units  
du <- depth_units(sp5)  
  
# set alternate units; e.g. inches  
depth_units(sp5) <- 'in'  
  
# replace original value (cm)  
depth_units(sp5) <- du
```

---

diagnostic\_hz,SoilProfileCollection-method  
*Retrieve diagnostic data from SoilProfileCollection*

---

**Description**

Get diagnostic feature data from SoilProfileCollection. Result is returned in the same data.frame class used to initially construct the SoilProfileCollection.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
diagnostic_hz(object)
```

**Arguments**

```
object          a SoilProfileCollection
```

---

```
diagnostic_hz<-      Add Data to Diagnostic Features Slot
```

---

**Description**

Diagnostic feature data in an object inheriting from `data.frame` can easily be added via `merge` (LEFT JOIN). There must be one or more same-named columns containing profile ID on the left and right hand side to facilitate the join: `diagnostic_hz(spc) <- newdata`

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection'
diagnostic_hz(object) <- value
```

**Arguments**

```
object          A SoilProfileCollection
value           An object inheriting data.frame
```

**Examples**

```
# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# assign two profiles a zone related to the mollic epipedon
newdata <- data.frame(id = c("hon-1", "hon-17"),
                      featkind = "fixed-depth surface sample",
                      featdept = 0,
                      featdepb = 18)

# do left join
diagnostic_hz(sp2) <- newdata

# inspect site table: newvalue TRUE only for horizons
# with top depth equal to zero
diagnostic_hz(sp2)
```

---

 dice, SoilProfileCollection-method

*Efficient Slicing of SoilProfileCollection Objects*

---

## Description

Cut ("dice") soil horizons into 1-unit thick slices. This function replaces `aqp::slice()`, which will be deprecated in aqp 2.0.

## Usage

```
## S4 method for signature 'SoilProfileCollection'
dice(
  x,
  fm = NULL,
  SPC = TRUE,
  pctMissing = FALSE,
  fill = FALSE,
  strict = TRUE,
  byhz = TRUE,
  verbose = FALSE
)
```

## Arguments

<code>x</code>	a <code>SoilProfileCollection</code> object
<code>fm</code>	optional formula describing top depths and horizon level attributes to include: <code>integer.vector ~ var1 + var2 + var3</code> or <code>integer.vector ~ .</code> to include all horizon level attributes. Specification of <code>integer.vector</code> forces <code>fill = TRUE</code> . When <code>NULL</code> profiles are "diced" to depth and results will include all horizon level attributes. Note on interpretation of <code>integer.vector</code> (slice tops)
<code>SPC</code>	return the diced <code>SoilProfileCollection</code> , if <code>FALSE</code> a <code>data.frame</code> of horizon-level attributes
<code>pctMissing</code>	compute "percent missing data" by slice (when <code>TRUE</code> expect 6-8x longer run time)
<code>fill</code>	logical, fill with empty placeholder horizons in gaps within profiles, and/or, above/below interval specified in <code>fm</code> . Automatically set to <code>TRUE</code> when LHS of <code>fm</code> is specified. Backwards compatibility with <code>slice</code> is maintained by setting <code>fill = TRUE</code> with or without <code>fm</code> .
<code>strict</code>	perform horizon depth logic checking / flagging / removal
<code>byhz</code>	Evaluate horizon depth logic at the horizon level ( <code>TRUE</code> ) or profile level ( <code>FALSE</code> ). Invalid depth logic invokes <code>HzDepthLogicSubset</code> which removes offending profiles or horizon records.
<code>verbose</code>	Print information about object size/memory usage. Default: <code>FALSE</code>

**Details**

For large and potentially messy collections that may include missing horizon depth logic errors, consider using `repairMissingHzDepths()` before `dice()`. Consider using `accumulateDepths()` before invoking `dice()` on collections that may contain old-style O horizon notation (e.g. 5-0cm).

**Value**

a `SoilProfileCollection` object, or `data.frame` when `SPC = FALSE`

**Author(s)**

D.E. Beaudette and A.G. Brown

**See Also**

[repairMissingHzDepths\(\)](#), [accumulateDepths\(\)](#), [fillHzGaps\(\)](#)

---

dissolve\_hz

*Dissolving horizon boundaries by grouping variables*

---

**Description**

This function dissolves or combines horizons that have a common set of grouping variables. It only combines those horizon records that are sequential (e.g. share a horizon boundary). Thus, it can be used to identify discontinuities in the grouping variables along a profile and their unique depths. It is particularly useful for determining the depth to the top or bottom of horizons with a specific category, and should be simpler than previous methods that require aggregating over profiles.

**Usage**

```
dissolve_hz(
  object,
  by,
  id = "peiid",
  hztop = "hzdept",
  hzbot = "hzdepb",
  collapse = FALSE,
  order = FALSE
)
```

**Arguments**

<code>object</code>	a <code>data.frame</code>
<code>by</code>	character: column names, to be used as grouping variables, within the object.
<code>id</code>	character: column name of the pedon ID within the object.
<code>hztop</code>	character: column name of the horizon top depth within the object.

hzbtop	character: column name of the horizon bottom depth in the object.
collapse	logical: indicating whether to not combine grouping variables before dissolving.
order	logical: indicating whether or not to order the object by the id, hztop, and hzbtop columns. #'

### Details

This function assumes the profiles and horizons within the object follow the logic defined by `checkHzDepthLogic` (e.g. records are ordered sequentially by id, hztop, and hzbtop and without gaps). If the records are not ordered, set the `order = TRUE`.

### Value

A data.frame with the original id, by grouping variables, and non-consecutive horizon depths.

### Author(s)

Stephen Roecker

### See Also

### Examples

```
# example 1
data(jacobs2000)
spc <- jacobs2000

spc$dep_5 <- spc$depletion_pct >=5
spc$genhz <- generalize.hz(spc$name, c("A", "E", "B", "C"), c("A", "E", "B", "C"))
h <- horizons(spc)

test <- dissolve_hz(h, by = c("genhz", "dep_5"), id = "id", hztop = "top", hzbtop = "bottom")

vars <- c("id", "top", "bottom", "genhz", "dep_5")
h[h$id == "92-1", vars]
test[test$id == "92-1", ]

# example 2
df <- data.frame(
  peiid = 1,
  hzdept = c(0, 5, 10, 15, 25, 50),
  hzdepb = c(5, 10, 15, 25, 50, 100),
  hzname = c("A1", "A2", "E/A", "2Bt1", "2Bt2", "2C"),
  genhz = c("A", "A", "E", "2Bt", "2Bt", "2C"),
  texcl = c("sil", "sil", "sil", "sl", "sl", "s")
)
```

```
df

dissolve_hz(df, c("genhz", "texcl"))
dissolve_hz(df, c("genhz", "texcl"), collapse = TRUE)

test <- dissolve_hz(df, "genhz")
subset(test, value == "2Bt")
```

---

duplicate

*Duplicate Profiles of a SoilProfileCollection*

---

### Description

A simple function to duplicate the contents of a `SoilProfileCollection` object. Old profile IDs are saved as a site-level attribute (`oldID`) and new IDs are generated using a numeric serial number.

### Usage

```
duplicate(x, times = 3, oldID = ".oldID")
```

### Arguments

<code>x</code>	a <code>SoilProfileCollection</code> object with 1 or more profiles
<code>times</code>	requested number of copies
<code>oldID</code>	site-level attribute used to store the original profile IDs

### Value

a `SoilProfileCollection` object

### Author(s)

D.E. Beaudette

### Examples

```
# sample data
data('sp4')

# promote to SPC
depths(sp4) <- id ~ top + bottom

# duplicate each profile 2 times
d <- duplicate(sp4, times = 2)

# graphical check
par(mar = c(0, 0, 3, 1))
```

```
plotSPC(d, color = 'Ca', width = 0.25)
```

---

electroStatics\_1D      *Label placement based on a simulation of electrostatic forces*

---

## Description

This function attempts to move labels along a 1D coordinate system such that overlap (as specified by threshold) is minimized. An electrostatic simulation applies forces of repulsion between labels that are within thresh (e.g. overlapping) and forces of attraction to a uniformly spaced sequence to iteratively perturb affected labels until either no overlap is reported, or a maximum number of iterations (maxIter) has been reached.

## Usage

```
electroStatics_1D(
  x,
  thresh,
  q = 1,
  chargeDecayRate = 0.01,
  QkA_GrowthRate = 0.05,
  maxIter = 100,
  tiny = 1e-04,
  const = 0.001,
  trace = FALSE,
  ...
)
```

## Arguments

x	numeric vector, pre-sorted sorted, without duplication, describing 1D label (particle) configuration
thresh	numeric, overlap threshold, same as in <a href="#">fixOverlap()</a>
q	numeric, electrical charge (typically between 0.1 and 2)
chargeDecayRate	numeric, exponential decay rate constant for q as a function of iteration i
QkA_GrowthRate	numeric, growth rate constant for Qk applied to attraction to uniform spacing of labels, invoked when rank order is violated during the simulation
maxIter	integer, maximum number of iterations before giving up
tiny	numeric, 0-values replaced by this number to avoid division by 0 and infinite forces
const	numeric, empirical constant added to the 1D electrostatic force equation to dampen oscillation: $(Qk * Q1 * Q2) / (d^{ex} + const)$
trace	logical, include diagnostic output
...	not used, absorbs additional arguments to <a href="#">fixOverlap()</a>

**Details**

Difficult overlap problems can be addressed by reducing thresh and increasing q. Large values of q can lead to chaotic results.

This function will generate unpredictable output when x contains duplicate values.

This function requires input to be pre-sorted, although interesting "artistic" simulations will often result from unsorted x.

**Value**

When trace = TRUE a list, otherwise numeric vector with converged attribute.

**Author(s)**

D.E. Beaudette and K.C. Thompson

**See Also**

[fixOverlap\(\)](#), [SANN\\_1D\(\)](#)

**Examples**

```
# vector of object locations, with potential overlap
x <- c(1, 2, 3, 3.3, 3.8, 5, 6, 7, 8, 9, 10)

# full diagnostic output
z <- electroStatics_1D(x, thresh = 0.65, trace = TRUE, q = 1)
txt <- sprintf("Converged %s (%s iterations)", z$converged, length(z$cost))

plot(
  seq_along(z$cost),
  z$cost,
  las = 1,
  xlab = 'Iteration',
  ylab = 'Overlap Cost',
  type = 'b',
  main = txt
)

abline(h = 0, lty = 2, col = 2)

# final configuration only
xnew <- electroStatics_1D(x, thresh = 0.65, q = 1)

# check for convergence
attr(xnew, 'converged')

# compare original vs. modified
data.frame(orig = x, new = round(xnew, 2))
```

---

`equivalentMunsellChips`*Identify "equivalent" (whole number value/chroma) Munsell chips*

---

## Description

Uses a pre-calculated lookup list (`equivalent_munsell`) based on pair-wise CIE2000 contrast ( $dE_{00}$ ) of LAB color with D65 illuminant for all whole value/chroma "chips" in the `aqp:munsell` data set.

The intention is to identify Munsell chips that may be "functionally equivalent" to some other given whole value/chroma chip elsewhere in the Munsell color space – as discretized in the `aqp:munsell` data table. This basic assumption needs to be validated against your end goal: probably by visual inspection of some or all of the resulting sets. See `colorContrast` and `colorContrastPlot`.

"Equivalent" chips table are based (fairly arbitrarily) on the 0.001 probability level of  $dE_{00}$  (default Type 7 quantile) within the upper triangle of the  $8467 \times 8467$  contrast matrix. This corresponds to a  $dE_{00}$  contrast threshold of approximately 2.15.

## Usage

```
equivalentMunsellChips(hue = NULL, value = NULL, chroma = NULL)
```

## Arguments

hue	A character vector containing Munsell hues
value	A numeric vector containing Munsell values (integer only)
chroma	A numeric vector containing Munsell chromas (integer only)

## Value

A named list; Each list element contains a data.frame with one or more rows of "equivalent" Munsell, RGB and LAB color coordinates from `munsell` data set.

---

equivalent\_munsell      *Indices of "equivalent" Munsell chips in the munsell data set*

---

## Description

A pre-calculated lookup list (made with `farver::compare_colour`) based on pair-wise color contrast (CIE2000 or dE00) evaluated over all "chips" in the `aqp:munsell` data set.

The intention is to identify Munsell chips that may be "functionally equivalent" to some other given whole chip elsewhere in the Munsell color space – as discretized in the `aqp:munsell` lookup table.

"Equivalent" chips are based (fairly arbitrarily) on the 0.001 probability level of dE00 (default Type 7 quantile) within the upper triangle of the 8467x8467 contrast matrix. This corresponds to a dE00 threshold of approximately 2.15.

This is a naive (to the subtleties of human color perception, and overall magnitude of contrast between some of the "chips") but computationally consistent approach. Using the lookup list, as opposed to manual contrast via e.g. `farver::compare_colour` may have some benefits for efficiency in certain applications where the exact contrast value is not as important as the concept of having some threshold that is non-zero, but very small.

## Usage

```
data(equivalent_munsell)
```

## Format

A named list with 8467 elements, each containing a numeric vector of indices corresponding to the `munsell` data set, which has 8467 rows (unique, whole-number chips). Names have the format HUE VALUE/CHROMA, e.g. "7.5YR 4/4"

```

---

```
estimateAWC
```

---

```
Estimate available water capacity for fine-earth fraction
```

---

**Description**

Estimate available water capacity for fine-earth fraction

**Usage**

```
estimateAWC(texcl, omcl, precision = 2, FUN = mean, ...)
```

**Arguments**

texcl	character, USDA textural class fine earth fraction
omcl	integer, Organic matter class. 1: less than 1.5 percent, 2: less than 5, 3: greater than 5
precision	integer, Number of decimal places in result default: 2
FUN	Function for interpolating between table values default: mean
...	Additional arguments to FUN

**Value**

A numeric vector double containing estimated available water capacities for fine-earth fraction.

**Examples**

```
# organic matter, loam texture, low medium and high OM
base.awc <- estimateAWC(c("1","1","1"), c(1, 2, 3), na.rm = TRUE)
base.awc
```

---

estimatePSCS	<i>Estimate boundaries of the particle size control section (U.S Soil Taxonomy; 12th edition)</i>
--------------	---

---

### Description

Estimates the upper and lower boundary of the particle size control section by applying a programmatic version of the particle size control section key from the Keys to Soil Taxonomy (12th edition).

### Usage

```
estimatePSCS(
  p,
  hzdesgn = "hzname",
  clay.attr = "clay",
  texcl.attr = "texcl",
  tax_order_field = "tax_order",
  bottom.pattern = "Cr|R|Cd",
  simplify = TRUE,
  ...
)
```

### Arguments

p	A SoilProfileCollection
hzdesgn	Name of the horizon attribute containing the horizon designation. Default 'hzname'
clay.attr	Name of the horizon attribute containing clay contents. Default 'clay'
texcl.attr	Name of the horizon attribute containing textural class (used for finding sandy textures). Default 'texcl'
tax_order_field	Name of the site attribute containing taxonomic order; for handling PSCS rules for Andisols in lieu of lab data. May be NA or column missing altogether, in which case Andisol PSC possibility is ignored.
bottom.pattern	Regular expression pattern to match a root-restrictive contact. Default matches Cr, R or Cd. This argument is passed to both estimateSoilDepth and getArgillicBounds.
simplify	Return a length 2 vector with upper and lower boundary when p has length 1? Default TRUE.
...	additional arguments are passed to getArgillicBounds()

### Details

Requires information to identify argillic horizons (clay contents, horizon designations) with getArgillicBounds() as well as the presence of plow layers and surface organic soil material. Any getArgillicBounds() arguments may be passed to estimatePSCS.

Requires information on taxonomic order (to handle andisols).

**WARNING:** Soils in arenic or grossarenic subgroups, with fragipans, or with strongly contrasting PSCs may not be classified correctly. The author would welcome a dataset to develop this functionality for.

### Value

A numeric vector (when `simplify=TRUE`) containing the top and bottom depth of the particle size control section. First value is top, second value is bottom. If `p` contains more than one profile, the result is a `data.frame` with profile ID plus PSCS top and bottom depths.

### Author(s)

Andrew Gene Brown

### References

Soil Survey Staff. 2014. Keys to Soil Taxonomy, 12th ed. USDA-Natural Resources Conservation Service, Washington, DC.

`getArgillicBounds`, `getSurfaceHorizonDepth`

### Examples

```
data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1
attr <- 'prop' # clay contents
foo <- estimatePSCS(p, hzdesgn='name', clay.attr = attr, texcl.attr="texture")
foo
```

---

estimateSoilColor      *Estimate dry soil colors from moist soil colors and vice versa.*

---

### Description

Soil color is typically described at dry and moist conditions. This function attempts to estimate soil color at dry or moist condition when one is missing. Estimation proceeds as:

- convert Munsell notation to CIELAB color coordinates via `munse112rgb()`
- apply scaling, rotation, and translation parameters in CIELAB color space

- convert CIELAB to sRGB coordinates
- locate closest Munsell chip to sRGB coordinates via col2munsell()

Estimation of dry from moist soil color state is not guaranteed to be symmetric with estimation of moist from dry.

### Usage

```
estimateSoilColor(hue, value, chroma, sourceMoistureState = c("dry", "moist"))
```

### Arguments

hue	vector of Munsell hue ('10YR', '2.5Y', etc.)
value	vector of Munsell value (2,2.5 2.5, 3, 5, 6, etc.)
chroma	vector of Munsell chroma (2, 3, 4, etc.)
sourceMoistureState	character, source colors are either 'dry' or 'moist'

### Details

Scaling, rotation, and translation parameters for shifting between dry <-> moist CIELAB coordinates was determined using `vegan::procrustes()`, from those official series descriptions (OSD) where moist and dry soil colors were available.

Estimates for colors having a (dry or moist) Munsell value of 10 are not likely correct.

This is still a work in progress.

### Value

data.frame of estimated colors in Munsell notation. The sigma column contains CIE2000 color contrast metric values describing the perceptual distance between estimated color in CIELAB coordinates and closest Munsell chip.

### Author(s)

D.E. Beaudette

### Examples

```
# keep examples from using more than 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

estimateSoilColor(hue = '10YR', value = 3, chroma = 3, sourceMoistureState = 'moist')

# note that estimation is not symmetric
estimateSoilColor(hue = '10YR', value = 5, chroma = 3, sourceMoistureState = 'dry')
```

---

estimateSoilDepth	<i>Estimate Soil Depth</i>
-------------------	----------------------------

---

### Description

Estimate the soil depth of a single profile within a SoilProfileCollection object. This function would typically be called by [profileApply](#).

### Usage

```
estimateSoilDepth(
  f,
  name = hzdesgnname(f),
  p = "Cr|R|Cd",
  selection = min,
  no.contact.depth = NULL,
  no.contact.assigned = NULL
)
```

### Arguments

<code>f</code>	SoilProfileCollection object of length 1, e.g. a single profile
<code>name</code>	name of the column that contains horizon designations
<code>p</code>	REGEX pattern for determining "contact", or depth to some morphologic feature (e.g. Bt)
<code>selection</code>	an R function applied in the presence of multiple matching horizons: min (default), max, mean, etc.
<code>no.contact.depth</code>	in the absence of contact matching <code>p</code> , a depth at which we can assume a standard depth-to-contact
<code>no.contact.assigned</code>	value assigned when no contact is encountered at or below <code>no.contact.depth</code>

### Details

The choice of a selection function usually follows:

min: the top of the first matching horizon, max: the top bot the last matching horizon, or possibly mean: somewhere in-between.

### Value

single value representing the depth to contact or `no.contact.assigned`

### Author(s)

D.E. Beaudette and J.M. Skovlin

# top of the first Cd
estimateSoilDepth(d, name = 'name')

# top of the first Cd
estimateSoilDepth(d, name = 'name', selection = min)

# top of the R
estimateSoilDepth(d, name = 'name', selection = max)

# top of the second Cd
estimateSoilDepth(d, name = 'name', selection = max, p = 'Cd')

## another example

data(sp1)
depths(sp1) <- id ~ top + bottom

# init horizon designation
hzdesgnname(d) <- 'name'

# apply to each profile in a collection, and save as site-level attribute
sp1$depth <- profileApply(sp1, estimateSoilDepth, name='name')
```

```

# this function can be used to "find" depth to any feature
# that can be defined via REGEX pattern matching on the horizon name
# for example, locate the depth to the top "Bt" horizon
# returning NA when there is no match
sp1$top_Bt <- profileApply(
  sp1, estimateSoilDepth,
  name='name',
  p='Bt',
  no.contact.depth=0,
  no.contact.assigned=NA
)

# reduced margins
par(mar=c(1,1,1,2))
# adjust default y-offset and depth scaling for following examples
plotSPC(sp1, y.offset=10, scaling.factor=0.5)

# get plotting parameters for profile widths and depth scaling factors
lsp <- get("last_spc_plot", envir = aqp.env)

# positions on x-axis, same for both depth and top "Bt" horizon
x.positions <- (1:length(sp1)) - lsp$width

# annotate contact with unicode right-arrow
# y-position is adjusted based on plot y-offset and scaling factor
y.positions <- lsp$y.offset + (sp1$depth * lsp$scaling.factor)
text(x.positions, y.positions, '\u2192', col='red', adj=1, cex=1.25, lwd=2)

# annotate top "Bt" depth with unicode right-arrow
# y-position is adjusted based on plot y-offset and scaling factor
y.positions <- lsp$y.offset + (sp1$top_Bt * lsp$scaling.factor)
text(x.positions, y.positions, '\u2192', col='blue', adj=1, cex=1.25, lwd=2)

## Not run:
# sample data
data(gopheridge, package='soilDB')

# run on a single profile
estimateSoilDepth(gopheridge[1, ], name = 'hzname')

# apply to an entire collection
profileApply(gopheridge, estimateSoilDepth, name = 'hzname')

## End(Not run)

```

**Description**

Data-driven evaluation of generalized horizon labels using nMDS and silhouette width.

**Usage**

```
evalGenHZ(
  obj,
  genhz = GHL(obj, required = TRUE),
  vars,
  non.matching.code = "not-used",
  stand = TRUE,
  trace = FALSE,
  metric = "euclidean"
)
```

**Arguments**

<code>obj</code>	a <code>SoilProfileCollection</code> object
<code>genhz</code>	name of horizon-level attribute containing generalized horizon labels
<code>vars</code>	character vector of horizon-level attributes to include in the evaluation
<code>non.matching.code</code>	code used to represent horizons not assigned a generalized horizon label
<code>stand</code>	standardize variables before computing distance matrix (default = TRUE), passed to <a href="#">daisy</a>
<code>trace</code>	verbose output from passed to <a href="#">isoMDS</a> , (default = FALSE)
<code>metric</code>	distance metric, passed to <a href="#">daisy</a>

**Details**

Non-metric multidimensional scaling is performed via [isoMDS](#). The input distance matrix is generated by [daisy](#) using (complete cases of) horizon-level attributes from `obj` as named in `vars`.

Silhouette widths are computed via [silhouette](#). The input distance matrix is generated by [daisy](#) using (complete cases of) horizon-level attributes from `obj` as named in `vars`. Note that observations with `genhz` labels specified in `non.matching.code` are removed filtered before calculation of the distance matrix.

**Value**

a list is returned containing:

**horizons** `c('mds.1', 'mds.2', 'sil.width', 'neighbor')`

**stats** mean and standard deviation of `vars`, computed by generalized horizon label

**dist** the distance matrix as passed to [isoMDS](#)

---

evalMissingData

*Evaluate Missing Data within a SoilProfileCollection*

---

**Description**

Evaluate missing data within a SoilProfileCollection object

Data completeness is evaluated by profile or by horizon. Profile-level evaluation is based on the thickness of horizons (method = absolute) with complete horizon-level attributes (vars), optionally divided by the total thickness (method = relative). The REGEX pattern (p) is used to filter non-soil horizons from the calculation.

**Usage**

```
evalMissingData(
  x,
  vars,
  name = hzdesgnname(x),
  p = "Cr|R|Cd",
  method = c("relative", "absolute", "horizon")
)
```

**Arguments**

x	SoilProfileCollection object
vars	character vector, naming horizon-level attributes in x
name	character, the name of a horizon-level attribute where horizon designations are stored, defaults to hzdesgnname(x)
p	character, REGEX pattern used to match non-soil horizons
method	character, one of: 'relative' (proportion of total) depth, 'absolute' depth, or 'horizon' (fraction not-missing by horizon)

**Value**

A vector values ranging from 0 to 1 (method = 'relative') or 0 to maximum depth in specified depth units (method = 'absolute') representing the quantity of non-missing data (as specified in vars) for each profile. When method = 'horizon' a non-missing data fraction is returned for each horizon.

**Author(s)**

D.E. Beaudette

**Examples**

```
# example data
data("jacobs2000")

# fully populated
plotSPC(jacobs2000, name.style = 'center-center',
        cex.names = 0.8, color = 'time_saturated')

# missing some data
plotSPC(jacobs2000, name.style = 'center-center',
        cex.names = 0.8, color = 'concentration_color')

# very nearly complete

  line = 0, cex.axis = 0.75
)

# add absolute completeness (cm)
axis(
  side = 1, at = 1:length(jacobs2000),
  labels = jacobs2000$data.complete.abs[new.order],
  line = 2.5, cex.axis=0.75
)

```

---

explainPlotSPC

*Visual Explanation for plotSPC*

---

## Description

Create a visual explanation for the many arguments to `plotSPC`. Call this function instead of `plotSPC`, all objects after `x` are passed on to `plotSPC`. Nearly all of the figures in the [Introduction to SoilProfileCollection Objects tutorial](#) are created with this function.

## Usage

```
explainPlotSPC(x, ...)
```

## Arguments

<code>x</code>	a <code>SoilProfileCollection</code> object
<code>...</code>	arguments passed to <code>plotSPC</code>

## Value

a list of internally-used ordering vectors and graphical offsets / scaling factors

**Author(s)**

D.E. Beaudette

**See Also**[plotSPC](#)**Examples**

```
# sample data
data(sp4)
depths(sp4) <- id ~ top + bottom

# proposed vector of relative positions, overlap likely
pos <- c(1, 1.1, 3, 4, 5, 5.2, 7, 8, 9, 10)

# try it
explainPlotSPC(sp4, name = 'name', relative.pos=pos)

# attempt to fix using an integer sequence, short-circuit will prevent adjustments
explainPlotSPC(sp4, name = 'name', relative.pos = fixOverlap(1:10))

# attempt to adjust using defaults
explainPlotSPC(sp4, name = 'name', relative.pos = fixOverlap(pos))

# attempt to adjust and tinker with defaults
explainPlotSPC(sp4, name = 'name', relative.pos = fixOverlap(pos, adj = 0.2))

# enforce larger space between
explainPlotSPC(sp4, name = 'name', relative.pos = fixOverlap(pos, thresh = 0.7))

# more complex adjustments required
pos <- c(1, 2, 3, 3.3, 5, 5.1, 5.5, 8, 9, 10)

# tinker
explainPlotSPC(sp4, name = 'name', relative.pos = pos)
explainPlotSPC(sp4, name = 'name', relative.pos = fixOverlap(pos))

explainPlotSPC(sp4, name = 'name', relative.pos = fixOverlap(pos,
thresh = 0.7))

explainPlotSPC(sp4, name = 'name',
relative.pos = fixOverlap(pos, thresh = 0.85, adj = 0.2)
)

# electrostatics: solution requires larger charge (q)
explainPlotSPC(sp4, name = 'name',
```

```
relative.pos = fixOverlap(pos, thresh = 0.85, method = 'E', q = 2)
)
```

---

fillHzGaps

*Find and Fill Horizon Gaps*

---

### Description

This function attempts to find "gaps" in the horizon records of a `SoilProfileCollection` object and fill with placeholder horizons (profile ID, horizon ID, to/bottom depths, all else NA). Missing horizon records between the top of each profile and `to_top`, or the bottom of each profile and `to_bottom` are treated as gaps when those arguments are not NULL. You can use this function to prepare a potentially messy `SoilProfileCollection` for subsequent analyses that are sensitive to horizon sequence inconsistencies or require a conformal "rectangle" of data spanning known depths.

Gaps are defined as:

- within each profile, for horizons `i` to `n_hz`:
- `bottom_i != top_{i+1}` (but only to `i = 1:(n_hz - 1)`)

### Usage

```
fillHzGaps(x, flag = TRUE, to_top = 0, to_bottom = max(x))
```

### Arguments

<code>x</code>	SoilProfileCollection object
<code>flag</code>	logical, flag empty horizons that have been added. default: TRUE
<code>to_top</code>	numeric, fill from shallowest top depth in each profile to specified depth? default: 0
<code>to_bottom</code>	numeric, fill from deepest bottom depth in each profile to specified depth? default: <code>aqp::max(x)</code>

### Value

a possibly modified `SoilProfileCollection` object

### Author(s)

A.G. Brown and D.E. Beaudette

**Examples**

```

data(sp4)
depths(sp4) <- id ~ top + bottom

# introduce depth logic errors
idx <- c(2, 6:7, 8, 12)
sp4$top[idx] <- NA

# check
horizons(sp4)[idx, ]

# create gaps by removing logic errors
x <- HzDepthLogicSubset(sp4, byhz = TRUE)

# check on removed horizons (hzID values)
metadata(x)$removed.horizons

# inspect
par(mar = c(0, 0, 0, 2))
plotSPC(x, width = 0.3, default.color = 'royalblue',
name = 'hzID', name.style = 'center-center', cex.names = 0.8,
cex.id = 0.66)

# fill gaps left by HzDepthLogicSubset()
z <- fillHzGaps(x, flag = TRUE)

# graphical check
plotSPC(z, width = 0.3, color = '.filledGap', name = 'hzID',
show.legend = FALSE, name.style = 'center-center', cex.names = 0.8,
cex.id = 0.66)

# fill top to 0 cm
z2 <- fillHzGaps(x, flag = TRUE, to_top = 0)
plotSPC(z2, width = 0.3, color = '.filledGap', name = 'hzID', show.legend = FALSE)

# fill bottom to max(SPC)
z3 <- fillHzGaps(x, flag = TRUE, to_top = 0, to_bottom = max(x))
plotSPC(z3, width = 0.3, color = '.filledGap', name = 'hzID', show.legend = FALSE)

## another example
data(sp4)
depths(sp4) <- id ~ top + bottom

# remove 1st horizons from profiles 1:4
idx <- sp4[, , .FIRST, .HZID]
replaceHorizons(sp4) <- horizons(sp4)[-idx[1:4], ]

# prepare for dice()
z <- fillHzGaps(sp4, to_top = 0, to_bottom = 50, flag = TRUE)

# empty-horizon padding is in place for formula interface to dice()

```

```
d <- dice(z, fm = 0:50 ~ .)
plotSPC(d, color = 'Ca', show.legend = FALSE)
plotSPC(d, color = '.filledGap', show.legend = FALSE)
```

---

 findOverlap

*Find Overlap within a Sequence*

---

### Description

Establish which elements within a vector of horizontal positions overlap beyond a given threshold

Desc.

### Usage

```
findOverlap(x, thresh)

overlapMetrics(x, thresh)
```

### Arguments

x	vector of relative horizontal positions, one for each profile
thresh	threshold defining "overlap", typically < 1
	@return a list:
	• idx: unique index to overlapping elements in x
	• ov: normalized overlap (see details)

### Value

unique index to affected (overlapping) elements in x

### Examples

```
x <- c(1, 2, 3, 3.4, 3.5, 5, 6, 10)
findOverlap(x, thresh = 0.5)

x <- c(1, 2, 3, 3.4, 3.5, 5, 6, 10)
overlapMetrics(x, thresh = 0.5)
```

---

fixOverlap	<i>Fix Overlap within a Sequence</i>
------------	--------------------------------------

---

**Description**

Fix Overlap within a Sequence

**Usage**

```
fixOverlap(x, thresh = 0.6, method = c("S", "E"), trace = FALSE, ...)
```

**Arguments**

x	vector of initial positions, pre-sorted
thresh	numeric, overlap threshold defined on the same scale as x
method	character vector, 'S' for simulated annealing via <a href="#">SANN_1D()</a> or 'E' for electrostatic simulation via <a href="#">electroStatics_1D()</a>
trace	logical, return full output
...	additional arguments to <a href="#">SANN_1D()</a> or <a href="#">electroStatics_1D()</a>

**Value**

When `trace = FALSE`, a vector of the same length as `x`, preserving rank-ordering and boundary conditions. When `trace = TRUE` a list containing the new sequence along with information about objective functions and decisions made during adjustment of `x`.

**See Also**

[electroStatics\\_1D\(\)](#), [SANN\\_1D\(\)](#)

**Examples**

```
s <- c(1, 2, 2.3, 4, 5, 5, 7)

# simulated annealing, solution is non-deterministic
fixOverlap(s, thresh = 0.6, method = 'S')

# electrostatics-inspired simulation of particles
# solution is deterministic
fixOverlap(s, thresh = 0.6, method = 'E')

# create a very busy profile with lots of possible overlapping
# depth annotation
x <- quickSPC(
  "SPC:AAA|BBB|CCC|D|EEEE|FF|GG|HH|I|I|JJ|KK|LL|M|N|O|P|QQQ|RR|S|TTTTT|U",
  interval = 1
```

```

)

# convert horizon ID to numeric
x$z <- as.numeric(x$hzID)

# plotSPC arguments

---

flagOverlappingHz      *Flag perfectly overlapping horizons within a SoilProfileCollection*

---

### Description

Flag perfectly overlapping horizons within a SoilProfileCollection

### Usage

```
flagOverlappingHz(x)
```

### Arguments

x                      a SoilProfileCollection object

### Value

logical vector with length (and order) matching the horizons of x

### Author(s)

D.E. Beaudette

### Examples

```

# two overlapping horizons
z <- data.frame(
  id = 'SPC',
  top = c(0, 25, 25, 50, 75, 100, 100),
  bottom = c(25, 50, 50, 75, 100, 125, 125)
)

# init SPC
depths(z) <- id ~ top + bottom

# flag perfectly overlapping horizons
z$.overlapFlag <- flagOverlappingHz(z)

# thematic sketches
plotSPC(z, color = '.overlapFlag', hz.depths = TRUE,
depth.axis = FALSE, cex.names = 0.85)

```

---

fragmentClasses      *Coarse Fragment Class Labels and Diameter*

---

### Description

This is a convenience function for accessing coarse fragment class labels and associated diameter (mm), as defined in various classification systems such as USDA, Unified, and AASHTO.

### Usage

```
fragmentClasses(  
  sys = c("usda_simplified", "usda", "international", "unified", "aashto",  
         "mod.wentworth"),  
  flat = FALSE,  
  rounded = FALSE  
)
```

### Arguments

sys	character, length 1. This is an abbreviated name used to select class labels and fragment diameter.
flat	logical. Fragments are flat, only used by USDA systems.
rounded	logical. Fragments are rounded, only used by AASHTO system.

### Value

named vector of fragment diameter in mm

### References

Schoeneberger, P.J., D.A. Wysocki, E.C. Benham, and Soil Survey Staff. 2012. Field book for describing and sampling soils, Version 3.0. Natural Resources Conservation Service, National Soil Survey Center, Lincoln, NE.

### See Also

### Examples

```
# use default system: "usda_simplified"  
fragmentClasses()  
fragmentClasses(flat = TRUE)  
  
fragmentClasses(sys = 'usda')  
fragmentClasses(sys = 'USDA', flat = TRUE)
```

```

fragmentClasses(sys = 'international')

fragmentClasses(sys = 'unified')

fragmentClasses(sys = 'aashto')
fragmentClasses(sys = 'aashto', rounded = TRUE)

fragmentClasses(sys = 'mod.wentworth')

```

---

fragmentSieve

*Sieve the Coarse Fraction of Soil*

---

### Description

Sieve applies thresholds to a numeric vector of fragment diameter values, returning fragment size classes. Particle diameter thresholds are evaluated as  $d < \text{threshold}$ .

### Usage

```

fragmentSieve(
  diameter,
  sieves = NULL,
  ordered = FALSE,
  prefix = "",
  new_names = NULL,
  ...
)

```

### Arguments

diameter	numeric. Vector of diameters of coarse fragments to "sieve". Default sieves are specified in millimeters.
sieves	leave as NULL to use fragment class labels and diameters defined by <a href="#">fragmentClasses()</a> , or a named vector of fragment diameters. See examples.
ordered	logical. Return as an ordered factor.
prefix	character. Add a prefix to result names? Default: "" adds no prefix. For example "para" might be used for size classes of pararock fragments.
new_names	Optional: apply new labels to result classes. Should match length of sieves.
...	additional arguments to <a href="#">fragmentClasses()</a> , such as sys, flat, and rounded, see examples.

### Value

character. Size class labels based on names of sieves, new\_names, and prefix (if specified).

fragmentSieve(c(10, 50), sieves = c(30, 70), ordered = TRUE)
```

---

generalize.hz

*Generalize Horizon Names*

---

**Description**

Generalize a vector of horizon names, based on new classes, and REGEX patterns. Or create a new column ghl in a SoilProfileCollection (requires a horizon designation name to be defined for the collection, see details)

**Usage**

```

generalize.hz(
  x,
  new,
  pattern,
  non.matching.code = "not-used",
  hzdepn = NULL,
  ordered = !missing(hzdepn),
  ...
)

## S4 method for signature 'character'
generalizeHz(
  x,
  new,
  pattern,
  non.matching.code = "not-used",
  hzdepn = NULL,
  ordered = !missing(hzdepn),
  ...
)

## S4 method for signature 'SoilProfileCollection'
generalizeHz(
  x,
  new,
  pattern,
  non.matching.code = "not-used",
  hzdepn = NULL,
  ordered = !missing(hzdepn),
  gh1 = "genhz",
  ...
)

```

**Arguments**

x	character vector of horizon names or a SoilProfileCollection object
new	character vector of generalized horizon labels (GHL)
pattern	character vector of REGEX patterns, same length as new
non.matching.code	character, label used for any horizon not matched by pattern
hzdepn	numeric vector of horizon mid-points; NA values in hzdepn will result in non.matching.code (or NA if not defined) in result
ordered	logical, TRUE when hzdepn argument is specified
...	additional arguments passed to grep() such as perl = TRUE for advanced REGEX
gh1	Generalized Horizon Designation column name (to be created/updated when x is a SoilProfileCollection)

**Details**

When *x* is a `SoilProfileCollection` the `gh1` column will be updated with the factor results. This requires that the "horizon designation name" metadata be defined for the collection to set the column for input designations.

**Value**

factor (possibly an ordered factor) of the same length as *x* (if character) or as number of horizons in *x* (if `SoilProfileCollection`)

# GHZ metadata is set
GHL(x)

```

---

genhzTableToAdjMat      *Convert cross-tabulation to adjacency matrix.*

---

### Description

Convert a cross-tabulation of e.g. original horizon designations vs. generalized horizon labels to adjacency matrix form.

### Usage

```
genhzTableToAdjMat(tab)
```

**Arguments**

tab                    table, cross-tabulation of original and generalized horizon labels e.g. table(original, genhz)

**Value**

matrix of numeric values

**Author(s)**

D.E. Beaudette

---

genSlabLabels                    *Generate Labels for Slabs*

---

**Description**

This method is used by `slab()` for generating labels that assign IDs to layers in a SoilProfileCollection

**Usage**

```
genSlabLabels(
  slab.structure = 1,
  max.d = NULL,
  n.profiles = NULL,
  spc = NULL,
  diced = NULL,
  ...
)
```

**Arguments**

slab.structure    A user-defined slab thickness (defined by an integer), or user-defined structure (numeric vector). See details for `slab()`.

max.d            Maximum depth

n.profiles       Number of profiles

spc              Optional: A SoilProfileCollection

diced            Optional: The `dice()`-ed horizon-level data.frame corresponding to spc

...              Additional arguments passed to `dice()` when spc is specified.

**Details**

The new routine used in aqp 2.0 requires that, at a minimum, the spc and slab.structure arguments be specified.

**Value**

factor. slab IDs, labels are the segment top and bottom depth separated by "-"

**See Also**

[slab\(\)](#)

---

get.increase.matrix    *Compute Pair-wise Distances of Soil Properties over Depth*

---

**Description**

Computes pair-wise distance matrix to determine where an attribute increases within a specified vertical distance threshold.

get.increase.depths performs the conversion of the square matrix output of get.increase.matrix back to horizon top depth for where criteria were met.

**Usage**

```
get.increase.matrix(p, attr, threshold.fun, vertical.distance)
```

```
get.increase.depths(p, attr, threshold.fun, vertical.distance)
```

**Arguments**

p	a SoilProfileCollection, containing a single profile
attr	horizon attribute name to get the "increase" of
threshold.fun	a function that returns the threshold (as a function of attr); may return a constant single value
vertical.distance	the vertical distance (determined from difference SPC top depth variable) within which increase must be met

**Details**

Uses matrix outer product to determine all pair-wise differences in attr for the horizons of p. Supplies attr to threshold.fun to determine the minimum value criterion to return TRUE in output matrix for an "increase". Also, computes all pair-wise distances in depth dimension to determine whether the vertical distance criteria have been met simultaneously with attr increase.

This function assumes that the threshold.fun supplied by the user returns either a constant or a vector of equal length to its input.

Note that the threshold.fun result is allowed to contain NA, but that will result in no output for affected cells.

get.increase.depths performs the conversion of the square matrix output of get.increase.matrix back to horizon top depth for where criteria were met.

Note that the threshold.fun result is allowed to contain NA, but that will result in no output for affected cells.

**Value**

Returns a square logical matrix reflecting where the increase criteria were met.

`get.increase.depths` converts to horizon dop depth by using above matrix output to determine depths where increase is met.

Returns a numeric vector of depths where the increase requirement is met. For the argillic, the first is the one of interest.

`get.increase.depths()` converts to horizon top depth by using above matrix output to determine depths where increase is met.

foo
```

---

`get.ml.hz`*Determine ML Horizon Boundaries*

---

**Description**

This function accepts input from `slab()` (a `data.frame`) along with a vector of horizon names, and returns a `data.frame` of the most likely horizon boundaries.

This function expects that `x` is a `data.frame` generated by `slab()`. If `x` was not generated by `slab()`, then `o.names` is required.

**Usage**

```
get.ml.hz(x, o.names = attr(x, which = "original.levels"))
```

**Arguments**

<code>x</code>	<code>data.frame</code> , output from <code>slab()</code>
<code>o.names</code>	an optional character vector of horizon designations that will be used in the final table

**Value**

A `data.frame` with the following columns:

- `hz`: horizon names
- `top`: horizon top depth
- `bottom`: horizon bottom depth
- `confidence`: integrated probability over thickness of each ML horizon, rounded to the nearest integer
- `pseudo.brier`: A "pseudo" Brier Score for a multi-class prediction, where the most-likely horizon label is treated as the "correct" outcome. Details on the calculation for traditional Brier Scores here: [https://en.wikipedia.org/wiki/Brier\\_score](https://en.wikipedia.org/wiki/Brier_score). Lower values suggest better agreement between ML horizon label and class-wise probabilities.
- `mean.H`: mean Shannon entropy (bits), derived from probabilities within each most-likely horizon. Larger values suggest more confusion within each ML.

# generate table of ML horizonation
get.ml.hz(a)

```

---

getArgillicBounds	<i>Estimate upper and lower boundary of argillic diagnostic subsurface horizon</i>
-------------------	--

---

**Description**

getArgillicBounds estimates the upper and lower boundary of argillic diagnostic subsurface horizon for a profile in a single-profile SoilProfileCollection object (p).

The upper boundary is where the clay increase threshold is met. The function uses `crit.clay.argillic` as the threshold function for determining whether a clay increase occurs and `get.increase.matrix` to determine whether the increase is met, whether vertical distance of increase is sufficiently small, and in which horizon.

**Usage**

```

getArgillicBounds(
  p,
  hzdesgn = "hzname",
  clay.attr = "clay",
  texcl.attr = "texcl",
  require_t = TRUE,
  bottom.pattern = "Cr|R|Cd",
  lower.grad.pattern = "^[2-9]*B*CB*[^rtd]*[1-9]*$",
  sandy.texture.pattern = "-S$|^S$|COS$|L[^V]FS$|[^L]VFS$|LS$|LFS$",
  vertical.distance = 30,
  simplify = TRUE,
  verbose = FALSE
)

```

**Arguments**

p	A SoilProfileCollection
hzdesgn	the name of the column/attribute containing the horizon designation; default="hzname"
clay.attr	the name of the column/attribute containing the clay content; default="clay"
texcl.attr	the name of the column/attribute containing the textural class (used for finding sandy horizons); default="texcl"
require_t	require a "t" subscript for positive identification of upper and lower bound of argillic? default: TRUE
bottom.pattern	regular expression passed to estimateSoilDepth to match the lower boundary of the soil. default is "Cr RICd" which approximately matches paralithic, lithic and densic contacts.
lower.grad.pattern	this is a pattern for adjusting the bottom depth of the argillic horizon upwards from the bottom depth of the soil. The absence of illuviation is used as a final control on horizon pattern matching.
sandy.texture.pattern	this is a pattern for matching sandy textural classes: -S\$ ^S\$ COS\$ L[^V]FS\$ [^L]VFS\$ LS\$ LFS\$
vertical.distance	Vertical distance in which clay increase must be met. Default 30 cm
simplify	Return a length 2 vector with upper and lower boundary when p has length 1? Default TRUE.
verbose	Print out information about 't' subscripts, sandy textures, plow layers and lower gradational horizons?

**Details**

The lower boundary is first approximated as the depth to a lithic/paralithic/densic contact, or some other horizon matchable by a custom regular expression pattern. Subsequently, that boundary is extended upwards to the end of "evidence of illuviation."

The depth to contact is estimated using 'bottom.pattern' "Cr|R|Cd" by default. It matches anything containing Cr, R or Cd.

The lower gradational horizon regular expression 'lower.grad.pattern' default is `^[2-9]*B*CB*[^rtd]*[1-9]*$`. It matches anything that starts with a lithologic discontinuity (or none) and a C master horizon designation. May contain B as second horizon designation in transitional horizon. May not contain 'r' or 't' subscript.

The minimum thickness of the argillic horizon is dependent on whether all subhorizons are "sandy" or not. The `sandy.texture.pattern` default `-S$|^S$|COS$|L[^V]FS$|[^L]VFS$|LS$|LFS$` captures USDA textural class fine earth fractions that meet "sandy" particle size class criteria.

There also is an option 'require\_t' to omit the requirement for evidence of eluviation in form of 't' subscript in 'hzdesgn'. Even if "t" subscript is not required for positive identification, the presence of lower gradational C horizons lacking 't' will still be used to modify the lower boundary upward from a detected contact, if needed. If this behavior is not desired, just set 'lower.grad.pattern' to something that will not match any horizons in your data.

### Value

Returns a numeric vector; first value is top depth, second value is bottom depth. If `as.list` is TRUE, returns a list with top depth named "ubound" and bottom depth named "lbound". If `p` has more than one profile or if `simplify = FALSE` the result is a data.frame containing profile ID, upper and lower boundary columns.

### Author(s)

Andrew G. Brown

### Examples

```
data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1
attr <- 'prop' # clay contents
foo <- getArgillicBounds(p, hzdesgn='name', clay.attr = attr, texcl.attr="texture")
foo
```

---

getCambicBounds

*Find all intervals that are potentially part of a Cambic horizon*

---

### Description

Find all intervals that are potentially part of a Cambic horizon excluding those that are part of an argillic horizon (defined either by depth interval or `getArgillicBounds()`).

There may be multiple cambic horizons (indexes) in a profile. Each cambic index has a top and bottom depth associated: `cambic_top` and `cambic_bottom`. This result is designed to be used for single profiles, or with `profileApply(..., frameify = TRUE)`

**Usage**

```
getCambicBounds(
  p,
  hzdesgn = guessHzDesgnName(p, required = TRUE),
  texcl.attr = guessHzTexClName(p, required = TRUE),
  clay.attr = guessHzAttrName(p, attr = "clay", c("total", "_r")),
  argi_bounds = NULL,
  d_value = "d_value",
  m_value = "m_value",
  m_chroma = "m_chroma",
  sandy.texture.pattern = "-S$|^S$|COS$|L[^V]FS$|[^L]VFS$|LS$|LFS$",
  ...
)
```

**Arguments**

p	A single-profile SoilProfileCollection
hzdesgn	Column name containing horizon designations.
texcl.attr	Arguments to getArgillicBounds()
clay.attr	Arguments to getArgillicBounds()
argi_bounds	Optional: numeric vector of length 2 with top and bottom of argillic; (Default: NULL)
d_value	Column name containing dry value. Default: d_value
m_value	Column name containing moist value. Default: m_value
m_chroma	Column name containing moist chroma Default: m_chroma
sandy.texture.pattern	this is a pattern for matching sandy textural classes: -S\$ ^S\$ COS\$ L[^V]FS\$ [^L]VFS\$ LS\$ LFS\$
...	Arguments to getArgillicBounds()

**Value**

A data.frame containing profile, cambic indexes, along with top and bottom depths.

**Author(s)**

Andrew G. Brown

**Examples**

```
# construct a fake profile
spc <- data.frame(id=1, taxsubgrp = "Lithic Haploxerepts",
  hzname = c("A", "AB", "Bw", "BC", "R"),
  hzdept = c(0, 20, 32, 42, 49),
  hzdepb = c(20, 32, 42, 49, 200),
  clay = c(19, 22, 22, 21, NA),
  texcl = c("1", "1", "1", "1", "br"),
  d_value = c(5, 5, 5, 6, NA),
```

```

m_value = c(2.5, 3, 3, 4, NA),
m_chroma = c(2, 3, 4, 4, NA))

# promote to SoilProfileCollection
depths(spc) <- id ~ hzdept + hzdepb
hzdesgname(spc) <- 'hzname'
hztexclname(spc) <- 'texcl'

# print results in table
getCambicBounds(spc)

```

---

getClosestMunsellChip *Get Approximate Munsell Chip*

---

### Description

Non-standard Munsell notation ('7.9YR 2.7/2.0') can be matched (nearest-neighbor, no interpolation) to the closest color within the munsell sRGB/CIELAB look-up table via `getClosestMunsellChip()`. A more accurate estimate of sRGB values from non-standard notation can be achieved with the [munsellinterpol](#) package. For example, conversion from Munsell to CIELAB, assuming a D65 illuminant via: `MunsellToLab('0.1Y 3.3/4.4', white='D65', adapt='Bradford')`.

### Usage

```
getClosestMunsellChip(munsellColor, convertColors = TRUE, ...)
```

### Arguments

`munsellColor` character vector of strings containing Munsell notation of color, e.g. '10YR 4/3'  
`convertColors` logical, should parsed Munsell colors be converted into sRGB values  
`...` further arguments to `munsell2rgb`

### Value

a `data.frame` when `convertColors=TRUE`, otherwise character vector

### Examples

```

# convert a non-standard color to closest "chip" in `munsell` look-up table
getClosestMunsellChip('7.9YR 2.7/2.0', convertColors = FALSE)

# convert directly to R color
getClosestMunsellChip('7.9YR 2.7/2.0')

# special case for 2.5 value -> no rounding, we have these records in the conversion LUT
getClosestMunsellChip('7.5YR 2.5/2', convertColors = FALSE)

```

```
getClosestMunsellChip('7.5YR 6.8/4.4', convertColors = FALSE)
```

---

getLastHorizonID	<i>Get IDs of Deepest Horizons by Profile</i>
------------------	---

---

### Description

Return horizon IDs of the deepest horizon within each profile of a SoilProfileCollection. IDs are returned in the same order as profile\_id(x). Horizon top depths are used because there are cases where bottom depths may be missing.

### Usage

```
getLastHorizonID(x)
```

### Arguments

x	a SoilProfileCollection
---	-------------------------

---

getSoilDepthClass	<i>Generate Soil Depth Class Matrix</i>
-------------------	---

---

### Description

Generate a boolean matrix of soil depth classes, actual soil depth class, and estimate of soil depth from a SoilProfileCollection object. Soil depths are estimated using pattern matching applied to horizon designations, by [estimateSoilDepth\(\)](#). The default REGEX pattern (p = 'Cr|R|Cd') will match most "contacts" described using the USDA / Soil Taxonomy horizon designation conventions.

### Usage

```
getSoilDepthClass(
  f,
  depth.classes = c(very.shallow = 25, shallow = 50, mod.deep = 100, deep = 150,
    very.deep = 10000),
  ...
)
```

### Arguments

f	a SoilProfileCollection object
depth.classes	a named vector of classes and depth breaks
...	arguments passed to <a href="#">estimateSoilDepth</a>

**Value**

a data.frame containing soil depth and depth class for each profile, see examples

**Author(s)**

D.E. Beaudette and J.M. Skovlin

**See Also**

[estimateSoilDepth](#)

**Examples**

```
data(sp1)
depths(sp1) <- id ~ top + bottom

# generate depth-class matrix

```

---

getSurfaceHorizonDepth

*Determine thickness of horizons (continuous from surface) matching a pattern*

---

**Description**

Find the thickness of horizon designations, or any other character patterns, that are continuous from the soil surface (depth = 0 or shallowest depth in profile).

**Usage**

```

getSurfaceHorizonDepth(
  p,
  pattern,
  hzdesgn = guessHzDesgnName(p),
  simplify = TRUE
)

getMineralSoilSurfaceDepth(
  p,
  hzdesgn = guessHzDesgnName(p),
  pattern = "O",
  simplify = TRUE
)

getPlowLayerDepth(
  p,
  hzdesgn = guessHzDesgnName(p),
  pattern = "^Ap[^b]*",
  simplify = TRUE
)

```

**Arguments**

p	a SoilProfileCollection
pattern	a regular expression pattern to match for all horizons to be considered part of the "surface".
hzdesgn	column name containing horizon designation. Default: guessHzDesgnName(p, required = TRUE).
simplify	logical. Return single profile results as vector (default: TRUE) or data.frame (FALSE)

**Details**

The horizon designation to match is specified with the regular expression pattern 'pattern'. All horizons matching that pattern, that are continuous from the soil surface, count towards the depth / thickness value that is ultimately returned. For instance: horizon designations: A1-A2-A3-C-Ab , would return A3 bottom depth given pattern = "^A[1-9]\*\$".

getSurfaceHorizonDepth is used by getPlowLayerDepth for matching Ap horizons; and, it is used by getMineralSoilSurfaceDepth to find the thickness of O horizons in lieu of lab data.

**Value**

a numeric value corresponding to the bottom depth of the last horizon matching 'pattern' that is contiguous with other matching horizons up to the soil surface. If length(p) > 1 then a *data.frame* containing profile ID, horizon ID, top or bottom depths, horizon designation and pattern.

**Author(s)**

Andrew G. Brown

**Examples**

```

library(aqp)
data(sp1, package = 'aqp')
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

p <- sp1[1]
q <- sp1[2]

# look at horizon designations in p and q
p$name
q$name

# thickness of all surface horizons containing A
getSurfaceHorizonDepth(p, pattern = 'A', hzdesgn = 'name')

# thickness of all surface horizons that start with A
getSurfaceHorizonDepth(p, pattern = '^A', hzdesgn = 'name')

# thickness of all surface horizons that start with A, and the A is not followed by B
getSurfaceHorizonDepth(p, pattern = '^A[^B]*', hzdesgn = 'name')

# thickness of all surface horizons that start with A
# followed by a number from _2_ to 9 (returns ZERO)
getSurfaceHorizonDepth(p, pattern = '^A[2-9]*', hzdesgn = 'name')

# getPLOWLayerDepth matches first two horizons in fake Ap horizon data with "buried Ap"
p$aphorizons <- c("Ap1", "Ap2", "AB", rep('C', nrow(p) - 4), "Apb")
getPLOWLayerDepth(p, hzdesgn = 'aphorizons')

# getMineralSoilSurfaceDepth matches first 3 horizons in fake O horizon data
p$ohorizons <- c("Oi1", "Oi2", "Oe", rep('C', nrow(p) - 4), "2C")
getMineralSoilSurfaceDepth(p, hzdesgn='ohorizons')

# matches first Oi horizon with original horizon designations of pedon 2
getMineralSoilSurfaceDepth(q, hzdesgn='name')

```

GHL

*Get or Set Generalized Horizon Label (GHL) Column Name***Description**

GHL(): Get column name containing generalized horizon labels

GHL&lt;-: Set generalized horizon label column name

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
GHL(object, required = FALSE)

## S4 replacement method for signature 'SoilProfileCollection'
GHL(object, required = FALSE) <- value
```

**Arguments**

object	a SoilProfileCollection
required	logical, is this attribute required? If it is, set to TRUE to trigger error on invalid value.
value	character, name of column containing generalized horizon labels

**Details**

Store the column name containing generalized horizon labels in the metadata slot of the SoilProfileCollection.

**Examples**

```
data(sp1)

# promote to SPC
depths(sp1) <- id ~ top + bottom

# set horizon designation column
GHL(sp1) <- "name"

# get horizon designation column
GHL(sp1)
```

---

glom, SoilProfileCollection-method

*Subset soil horizon data using a depth or depth interval*

---

**Description**

Make a "clod" of horizons from a SoilProfileCollection given a point or a depth interval to intersect. The interval [z1, z2] may be profile-specific (equal in length to p), or may be recycled over all profiles (if boundaries are length 1). For "point" intersection, z2 may be left as the default value NULL.

trunc() is a wrapper method (using S4 generic) for glom() where truncate=TRUE

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
glom(
  p,
  z1,
  z2 = NULL,
  ids = FALSE,
  df = FALSE,
  truncate = FALSE,
  invert = FALSE,
  fill = FALSE,
  modality = "all",
  drop = !fill,
  ...
)

## S4 method for signature 'SoilProfileCollection'
trunc(x, z1, z2, ...)
```

**Arguments**

p	A SoilProfileCollection
z1	numeric vector of top depth to intersect horizon (required). Can be an expression involving siteNames(p) or quoted column name. Should evaluate to numeric length 1 or length equal to length(p)
z2	numeric vector bottom depth of intersection interval (optional). Can also be an expression involving siteNames(p) or quoted column name. Should evaluate to numeric length 1, length equal to length(p) or NULL. Default: NULL is "point" intersection
ids	return only horizon IDs? default: FALSE
df	return a data.frame, by intersection with horizons(p)? default: FALSE
truncate	truncate horizon top and bottom depths to z1 and z2? default: FALSE
invert	get horizons <i>outside</i> the interval [z1, z2]? default: FALSE
fill	keep sites and preserve order for profiles that do not have horizons in interval by filling with a single horizon with NA top and bottom depth. default: FALSE
modality	default: "all" return all horizons; or modality = "thickest") to return the <i>thickest</i> horizon in interval. If multiple horizons have equal thickness, the first (shallowest) is returned.
drop	Inverted alias of fill for consistency with other methods. When drop=FALSE, filling occurs.
...	trunc(): additional arguments passed to glom()
x	A SoilProfileCollection

**Details**

"To glom" is "to steal" or to "become stuck or attached to". The word is related to the compound "glomalin", which is a glycoprotein produced by mycorrhizal fungi in soil.

The full depth range of horizons included within the interval are returned (a "ragged" SoilProfileCollection) unless the `truncate` argument is set as `TRUE`. Horizon intersection is based on unique ID `hziidname(spc)` and depth range of interest. Profiles that lack data in the range of interest will be dropped from the resulting SoilProfileCollection.

If inverting results with `invert`, it is possible that thick horizons (whose boundaries span wider than the specified interval) will be split into *two* horizons, where previously they were one. This may make the results from `ids = TRUE` different from what you expect, as they will be based on a profile with an "extra" horizon and re-calculated unique horizon ID (`hziidname(spc)`) "hziid".

**Value**

a SoilProfileCollection, data.frame, or a vector of horizon IDs. NULL if no result.

plot(p3, color = "prop", max.depth = 200)
abline(h = c(25, 100), lty = 2)

## profile-specific interval, using expressions evaluated within sp1@site

# calculate some new site-level variables containing target interval
sp1$glom_top <- (1:9) * 10
sp1$glom_bottom <- 10 + sp1$glom_top

# glom evaluates non-standard expressions using siteNames(sp1) column names
p4 <- glom(sp1, glom_top / 2, glom_bottom * 1.2, truncate = TRUE)

# inspect graphically
par(mar = c(1,1,3,1))
plot(p4, color = "prop", max.depth = 200)

# load sample data
data("sp3")

# promote to SPC
depths(sp3) <- id ~ top + bottom

### TRUNCATE all profiles in sp3 to [0,25]

# set up plot parameters
par(mfrow=c(2,1), mar=c(0,0,0,0))

# full profiles
plot(sp3)

# trunc'd profiles
plot(trunc(sp3, 0, 25))

```

**Description**

glomApply() is a function used for subsetting SoilProfileCollection objects by depth. It is a wrapper around glom which is intended to subset single-profile SPCs based on depth intervals/intersection.

glomApply works by accepting a function .fun as argument. This function is used on each profile to process a multi-profile SPC for input to glom (via profileApply). For each profile, .fun returns a 2-length numeric vector of top and bottom boundaries glom arguments: z1, z2.

glomApply provides the option to generate profile-specific glom depths for a large SPC and handles iteration and rebuilding of a subset SPC object. Optional arguments include: truncate to cut the boundaries to specified [z1, z2]; invert to the portion outside [z1, z2], modality to either "all" horizons or "thickest" horizon in the glom interval. ... are various expressions you can run on the individual profiles using NSE, similar to mutate.

**Usage**

```
glomApply(
  object,
  .fun = NULL,
  truncate = FALSE,
  invert = FALSE,
  modality = "all",
  ...,
  chunk.size = 100
)
```

**Arguments**

object	A SoilProfileCollection
.fun	A function that returns vector with top and bottom depth (z1 and z2 arguments to glom) for a single profile p (as passed by profileApply)
truncate	Truncate horizon top and bottom depths to [z1, z2]
invert	Truncate horizon top and bottom depths to [z1, z2] and then invert result?
modality	Aggregation method for glom result. Default "all": return all horizons; "thickest": return (shallowest) thickest horizon
...	A set of comma-delimited R expressions that resolve to a transformation to be applied to a single profile e.g glomApply(hzdept = max(hzdept) - hzdept) like aqp::mutate
chunk.size	Chunk size parameter for profileApply

**Value**

A SoilProfileCollection.

**Author(s)**

Andrew G. Brown.

**See Also**[glom trunc](#)[glom glomApply](#)**Examples**

```

# keep examples from using more than 2 cores

data(sp3)
depths(sp3) <- id ~ top + bottom

# init horizon designation column in metadata, used by estimateSoilDepth
hzdesgnname(sp3) <- 'name'

# constant depths, whole horizon returns by default
plot(glomApply(sp3, function(p) c(25,100)))

# constant depths, truncated
#(see aqp::trunc for helper function)
plot(glomApply(sp3, function(p) c(25,30), truncate = TRUE))

# constant depths, inverted
plot(glomApply(sp3, function(p) c(25,100), invert = TRUE))

# constant depths, inverted + truncated (same as above)
plot(glomApply(sp3, function(p) c(25,30), invert = TRUE, truncate=TRUE))

# random boundaries in each profile
plot(glomApply(sp3, function(p) round(sort(runif(2, 0, max(sp3))))))

# random boundaries in each profile (truncated)
plot(glomApply(sp3, function(p) round(sort(runif(2, 0, max(sp3))))), truncate = TRUE))

# calculate some boundaries as site level attributes
sp3$glom_top <- profileApply(sp3, getMineralSoilSurfaceDepth)
sp3$glom_bottom <- profileApply(sp3, estimateSoilDepth)

# use site level attributes for glom intervals for each profile
plot(glomApply(sp3, function(p) return(c(p$glom_top, p$glom_bottom))))

```

**Description**

grepSPC() is a shorthand function for subsetting SoilProfileCollections. For example, by filter(grepl(spc, ...)) or filter(stringr::str\_detect(spc, ...)). It provides pattern matching for a single text-based site or horizon level attribute.

**Usage**

```
grepSPC(object, attr, pattern, ...)
```

**Arguments**

object	A SoilProfileCollection
attr	A character vector (column in object) for matching patterns against.
pattern	REGEX pattern to match in attr
...	Additional arguments are passed to grep()

**Value**

A SoilProfileCollection.

**Author(s)**

Andrew G. Brown.

---

groupedProfilePlot      *Grouped Soil Profile Plot*

---

**Description**

Plot a collection of soil profiles, sorted by group.

The left-right ordering of groups can be adjusted by converting groups into a factor and explicitly setting factor levels. Alpha-numeric ordering is used for all other types.

**Usage**

```
groupedProfilePlot(
  x,
  groups,
  group.name.offset = -5,
  group.name.cex = 0.75,
  group.line.col = "RoyalBlue",
  group.line.lwd = 2,
  group.line.lty = 2,
  break.style = c("line", "arrow", "both"),
  break.offset = 0.5,
  arrow.offset = group.name.offset + 5,
```

```

    arrow.length = 0.1,
    ...
  )

```

### Arguments

<code>x</code>	a <code>SoilProfileCollection</code> object
<code>groups</code>	the name of a site-level attribute that defines groups, factor levels will influence plotting order
<code>group.name.offset</code>	vertical offset for group names, single numeric value or vector of offsets
<code>group.name.cex</code>	font size for group names
<code>group.line.col</code>	color for line that splits groups
<code>group.line.lwd</code>	width of line that splits groups
<code>group.line.lty</code>	style of line that splits groups
<code>break.style</code>	style of group boundaries: "line", "arrow", "both"
<code>break.offset</code>	horizontal offset used to place vertical breaks and/or arrows, shifted slightly to the right of default when <code>hz.depths=TRUE</code> is passed to <code>plotSPC()</code>
<code>arrow.offset</code>	vertical offset for "arrow" style boundaries, single numeric value or vector of offsets
<code>arrow.length</code>	value passed to arrows to define arrow head size
<code>...</code>	further arguments to <code>plotSPC</code>

group.line.lwd = 1)

## End(Not run)

```

---

groupSPC	<i>Store groupings within a profile collection.</i>
----------	---

---

### Description

Store groupings within a profile collection.

### Usage

```
groupSPC(object, ...)
```

### Arguments

object	SoilProfileCollection.
...	One or more expressions evaluated within the context of object that resolve to vectors that can be coerced to factor "groups."

---

guessGenHzLevels	<i>Guess Appropriate Ordering for Generalized Horizon Labels</i>
------------------	--

---

### Description

This function makes an (educated) guess at an appropriate set of levels for generalized horizon labels using the median of horizon depth mid-points.

### Usage

```
guessGenHzLevels(x, hz = GHL(x, required = TRUE))
```

### Arguments

x	a SoilProfileCollection object
hz	name of horizon-level attribute containing generalized horizon labels, see details

**Details**

This function is useful when groups of horizons have been generalized via some method other than `generalize.hz`. For example, it may be useful to generalize horizons using labels derived from slice depths. The default sorting of these labels will not follow a logical depth-wise sorting when converted to a factor. `guessGenHzLevels` does a good job of "guessing" the proper ordering of these labels based on median horizon depth mid-point.

**Value**

a list:

`levels` a vector of levels sorted by median horizon depth mid-point

`median.depths` a vector of median horizon mid-points

**Author(s)**

D.E. Beaudette

**See Also**

[generalize.hz](#)

**Examples**

```
# load some example data
data(sp1, package='aqp')

# upgrade to SoilProfileCollection
depths(sp1) <- id ~ top + bottom

# generalize horizon names
n <- c('O', 'A', 'B', 'C')
p <- c('O', 'A', 'B', 'C')
sp1$genhz <- generalize.hz(sp1$name, n, p)

# note: levels are in the order in which originally defined:
levels(sp1$genhz)

# generalize horizons by depth slice
s <- dice(sp1, c(5, 10, 15, 25, 50, 100, 150) ~ .)
s$slice <- paste0(s$top, ' cm')
# not a factor
levels(s$slice)

# the proper ordering of these new labels can be guessed from horizon depths
guessGenHzLevels(s, 'slice')

# convert to factor, and set proper order
s$slice <- factor(s$slice, levels=guessGenHzLevels(s, 'slice')$levels)
```

```
# that is better
levels(s$slice)
```

---

guessHzAttrName      *Guess Horizon Slot Column Names*

---

## Description

guessHzAttrName(): Guess the horizon column name where possible/preferred formative elements are known. There is a preference for records where more optional requirements are met to handle cases where there will be many matches. For example, working with soil data one might have "low, RV and high" total clay, as well as clay fractions. One could distinguish between these different measurements using standard formative elements for column names from the database of interest. Result is the first match in horizonNames(x) with the most required plus optional patterns matched.

e.g. guessHzAttrName(x, attr="clay", optional=c("total", "\_r")) matches (claytotal\_r == totalclay\_r) over (clay\_r == claytotal == totalclay) over clay.

guessHzDesgnName(): This follows the historic convention used by aqp::plotSPC() looking for "hzname" or other column names containing the regular expression "name". If the pattern "name" is not found, the pattern "desgn" is searched as a fallback, as "hzdesgn" or "hz\_desgn" are other common column naming schemes for horizon designation name.

guessHzTexClName(): This function is used to provide a texture class attribute column name to functions. It will use regular expressions to match "texcl" which is typically the texture of the fine earth fraction, without modifiers or in-lieu textures. Alternately, it will match "texture" for cases where "texcl" is absent (e.g. in NASIS Component Horizon).

## Usage

```
guessHzAttrName(x, attr, optional = NULL, verbose = TRUE, required = FALSE)
```

```
guessHzDesgnName(x, required = FALSE)
```

```
guessHzTexClName(x, required = FALSE)
```

## Arguments

x	A SoilProfileCollection
attr	A regular expression containing required formative element of attribute name.
optional	A character vector of regular expression(s) containing optional formative elements of attribute name.
verbose	A boolean value for whether to produce message output about guesses.
required	logical Default: FALSE. Is this attribute required? If it is, set to TRUE to trigger error on invalid value.

**Value**

Character containing horizon attribute column name. Result is the first match in horizonNames(x) with the most required plus optional patterns matched.

**Author(s)**

Andrew G. Brown

**Examples**

```
# a has the required attr pattern, but none of the optional
a <- data.frame(id = 1, top = c(0,10), bottom=c(10,40),
               clay=c(18,19))
depths(a) <- id ~ top + bottom

guessHzAttrName(a, attr="clay", optional=c("total", "_r"))

# b has required attr pattern, and one of the optional patterns
# notice that it also contains "clay" but preferentially matches more optional patterns
b <- data.frame(id = 1, top = c(0,10), bottom=c(10,40),
               clay=c(0.18,0.19), clay_r=c(18,19))
depths(b) <- id ~ top + bottom

guessHzAttrName(b, attr="clay", optional=c("total", "_r"))

# c has total and _r (both optional) on either side of clay
# having all of the optional patterns plus required is best evidence, and first
# column containing that combination will be returned
c <- data.frame(id = 1, top = c(0,10), bottom=c(10,40),
               totalclay_r=c(18,19), claytotal_r=c(0.18,0.19))
depths(c) <- id ~ top + bottom

guessHzAttrName(c, attr="clay", optional=c("total", "_r"))

a <- data.frame(id = 1, top = c(0,10), bottom=c(10,40), horizonname=c("A","Bw"))
depths(a) <- id ~ top + bottom

# store guess in metadata
hzdesgname(a) <- guessHzDesgnName(a)

# inspect result
hzdesgname(a)

a <- data.frame(id = 1, top = c(0,10), bottom=c(10,40), texture=c("A","Bw"))
depths(a) <- id ~ top + bottom

# store guess in metadata
hztexclname(a) <- guessHzTexClName(a)
```

```
# inspect result  
hztexclname(a)
```

---

harden.melanization     *Harden (1982) Melanization*

---

### Description

Calculate "melanization" component of "Profile Development Index" after Harden (1982) "A quantitative index of soil development from field descriptions: Examples from a chronosequence in central California". Accepts vectorized inputs for value and reference value to produce vector output. A convenient use case would be to apply this on a profile-specific basis, where the `value_ref` has a single value, and `value` is a vector of length equal to the number of horizons within the upper 100 cm.

### Usage

```
harden.melanization(value, value_ref)
```

### Arguments

<code>value</code>	numeric vector containing Munsell values
<code>value_ref</code>	A numeric vector containing Munsell value(s) for reference material

### Details

In Harden (1982), "melanization" is calculated relative to a reference parent material for all horizons within 100cm of the soil surface. In addition, several other non-color components are normalized relative to a maximum value and summed to obtain the overall Profile Development Index.

### Value

A numeric vector reflecting horizon darkening relative to a reference (e.g. parent) material.

### Author(s)

Andrew G. Brown

### References

}))

```

---

harden.rubification     *Harden (1982) Rubification*

---

### Description

Calculate "rubification" component of "Profile Development Index" after Harden (1982) "A quantitative index of soil development from field descriptions: Examples from a chronosequence in central California". Accepts vectorized inputs for hue and chroma to produce vector output.

In Harden (1982) "rubification" is calculated relative to a reference parent material. Several other non-color components are normalized relative to a maximum value and summed to obtain the overall Profile Development Index.

### Usage

```
harden.rubification(hue, chroma, hue_ref, chroma_ref)
```

### Arguments

hue	A character vector containing Munsell hues (e.g. "7.5YR")
chroma	A numeric vector containing Munsell chromas
hue_ref	A character vector containing Munsell hue(s) (e.g. "10YR") for reference material
chroma_ref	A numeric vector containing Munsell chroma(s) for reference material

### Value

A numeric vector reflecting horizon redness increase relative to a reference (e.g. parent) material.

### Author(s)

Andrew G. Brown

harmonize,SoilProfileCollection-method

*Harmonize a property by profile-level denormalization for convenient visualization or analysis of ranges*

---

## Description

It is sometimes convenient to be able to "denormalize" to a SoilProfileCollection with fewer attributes but more profiles. This is helpful wherever calculations are made on a profile basis and ranges or repeated measures are depicted with multiple attributes per soil horizon.

harmonize is most commonly used for creating "comparison" soil profile sketches with plotsPC—where the thematic attribute is derived from multiple data sources or summary statistics (such as quantiles of a property for Low-RV-High). However, the method more generally applies wherever one wants to alias between multiple columns containing "similar" data as input to an algorithm.

Data are "harmonized" to a common attribute names specified by the names of list elements in x.names. Profiles are essentially duplicated. In order to satisfy uniqueness constraints of the SoilProfileCollection, the label from the sub-elements of x.names are used to disambiguate profiles. A new column in the site table is calculated to reflect these groupings and facilitate filtering. See examples below.

## Usage

```

## S4 method for signature 'SoilProfileCollection'
harmonize(x, x.names, keep.cols = NULL, grp.name = "hgroup")

```

**Arguments**

x	A SoilProfileCollection.
x.names	a named list of character vectors specifying target names, profile ID suffixes and source attribute names for harmonization
keep.cols	a character vector of column names to keep unaltered from the horizon data
grp.name	a character vector with column name to store grouping variable in site table (default: "hgroup")

**Details**

If attributes reflecting the same or similar property within a soil layer have different names (e.g. socQ05, socQ50, socQ95) it is sometimes inconvenient to work with them as multiple attributes within the same profile. These similar attributes may need to be analyzed together, or in sequence by profile, displayed using the same name or using a common scale. It is also useful to be able to alias different data sources that have the same attributes with different names.

Each list element in x.names specifies a single "harmonization," which is comprised of one or more mappings from new to old. Each named "sub-element" of x.names specifies the name and attribute to use for updating the profile ID and site table of the duplicated profiles.

**Value**

A (redundant) SoilProfileCollection, with one profile for each set of harmonizations specified by x.names.

**Author(s)**

Andrew G. Brown

**Examples**

```
### single source "harmonization" of single-profile with range -> single attribute, multi-profile

# make some test data
spc <- pbindlist(lapply(1:10, random_profile, SPC = TRUE))

# assume that p1, p2 and p3 are the low RV and high quantiles for a hypothetical property "foo"
h1 <- harmonize(spc, x.names = list(foo = c(q05 = "p1", q50 = "p2", q95 = "p3")))

# inspect result
plot(h1, color = "foo")

# filter with calculated "harmonized group" to get just RV profiles
plot(subset(h1, hgroup == "q50"), color="foo")

### single source, two properties at once; with common labels: "method1" "method2"

# assume that p1, p2 are measurements by two (!=) methods for a hypothetical property "foo"
#           p3, p4 are measurements by same two methods for a hypothetical property "bar"
```

```

h3 <- harmonize(spc, x.names = list(foo = c(method1 = "p1", method2 = "p2"),
                                     bar = c(method1 = "p3", method2 = "p4")))
plot(h3, color = "foo")
plot(h3, color = "bar")
head(horizons(h3))

# a slight modification, "method 1" only used for "foo" and "method 3" for "bar"
h3 <- harmonize(spc, x.names = list(foo = c(method1 = "p1", method2 = "p2"),
                                     bar = c(method2 = "p3", method3 = "p4")))
plot(h3, color = "foo") # note the pattern of values missing for foo (*_method3)
plot(h3, color = "bar") # likewise for bar (*_method1)

#' the new labels need not match across harmonizations -- not sure how useful this is but it works
h3 <- harmonize(spc, x.names = list(foo = c(method1 = "p1", method2 = "p2"),
                                     bar = c(method3 = "p3", method4 = "p4")))
plot(h3, color = "foo") # note the pattern of values missing for foo (*_method 3 + 4)
plot(h3, color = "bar") # likewise for bar (*_method 1 + 2)

### two-source harmonization

# make test data
spc1 <- pbindlist(lapply(LETTERS[1:5], random_profile, SPC = TRUE))
spc2 <- pbindlist(lapply(letters[1:5], random_profile, SPC = TRUE))

h4 <- pbindlist(list(harmonize(spc1, list(foo = c(transect1 = "p4"))), # foo is p4 in dataset 1
                   harmonize(spc2, list(foo = c(transect2 = "p2")))) # foo is p2 in dataset 2

# same property with different name in two different datasets
plot(h4, color = "foo")

### many source harmonization

# make test datasets (n=10); highly redundant IDs (1:3 repeated)
spcs <- lapply(1:10, function(x) pbindlist(lapply(1:3, random_profile, SPC = TRUE)))

# randomly varying column name for demo (in each dataset, foo could be p1 thru p5)
rcolname <- paste0("p", round(runif(10, 0.5, 5.5)))

# iterate over data sources
bigspc <- pbindlist(lapply(1:length(spccs), function(i) {

  # assume each data source has a unique name for the property "foo"
  xn <- rcolname[i]

  # set names attribute to be equal to index i [creating unique profile IDs]
  # i.e. 2_10 will be profile ID 2 from 10th dataset
  names(xn) <- i

  # harmonize each data source, using unique column name and target name "foo"
  harmonize(spccs[[i]], x.names = list(foo = xn))
}))

# inspect a subset

```

```
plot(bigspc[1:30,], color = "foo")
```

---

hasDarkColors	<i>Find horizons with colors darker than a Munsell hue, value, chroma threshold</i>
---------------	---

---

## Description

hasDarkColors returns a boolean value by horizon representing whether darkness thresholds are met. The code is fully vectorized and deals with missing data and optional thresholds.

Default arguments are set up for "5-3-3 colors" – the basic criteria for Mollic/Umbric epipedon/mineral soil darkness. Any of the thresholds or column names can be altered. Any thresholds that are set equal to NA will be ignored.

## Usage

```
hasDarkColors(
  p,
  d_hue = NA,
  m_hue = NA,
  d_value = 5,
  d_chroma = NA,
  m_value = 3,
  m_chroma = 3,
  dhuenm = "d_hue",
  dvalnm = "d_value",
  dchrnm = "d_chroma",
  mhuenm = "m_hue",
  mvalnm = "m_value",
  mchrnm = "m_chroma"
)
```

## Arguments

p	A SoilProfileCollection.
d_hue	Optional: character vector of dry hues to match (default: NA)
m_hue	Optional: character vector of moist hues to match (default: NA)
d_value	Maximum value of dry value (default: 5)
d_chroma	Optional: Maximum value of dry chroma (default: NA)
m_value	Maximum value of moist value (default: 3)
m_chroma	Maximum value of moist chroma (default: 3)
dhuenm	Column name containing dry hue.
dvalnm	Column name containing dry value.

dchrom	Column name containing dry chroma.
mhuenm	Column name containing moist hue.
mvalnm	Column name containing moist value.
mchrom	Column name containing moist chroma.

**Value**

Boolean value (for each horizon in p) reflecting whether "darkness" criteria are met.

**Author(s)**

Andrew G. Brown

**Examples**

```
# construct a fake profile
spc <- data.frame(id=1, taxsubgrp = "Lithic Haploxeralfs",
  hzdesgn = c("A","AB","Bt","BCt","R"),
  hzdept = c(0, 20, 32, 42, 49),
  hzdepb = c(20, 32, 42, 49, 200),
  d_value = c(5, 5, 5, 6, NA),
  m_value = c(2.5, 3, 3, 4, NA),
  m_chroma = c(2, 3, 4, 4, NA))

# promote to SoilProfileCollection
depths(spc) <- id ~ hzdept + hzdepb

# print results in table
data.frame(id = spc[[idname(spc)]],
  hz_desgn = spc$hzdesgn,
  has_dark_colors = hasDarkColors(spc))
```

---

horizonColorIndices    *Horizon Color Indices*

---

**Description**

Calculate basic horizon-level color indices for a SoilProfileCollection. Basic indices do not require aggregation over the whole profile or comparison to a "reference" (e.g. parent material) color. Includes Hurst (1977) Redness Index, Barron-Torrent Redness Index (1986) and Buntley-Westin Index (1965). This is a wrapper method around several horizon-level indices. See the individual functions for more details.

**Usage**

```
horizonColorIndices(p, hue = "m_hue", value = "m_value", chroma = "m_chroma")
```

**Arguments**

p	A SoilProfileCollection
hue	Column name containing moist hue; default: "m_hue"
value	Column name containing moist value; default: "m_value"
chroma	Column name containing moist chroma; default: "m_chroma"

**Value**

A data.frame containing unique pedon and horizon IDs and horizon-level color indices.

**Author(s)**

Andrew G. Brown

**See Also**

[hurst.redness](#) [barron.torrent.redness.LAB](#) [buntley.westin.index](#)

**Examples**

```
# keep examples from using more than 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

data(sp1)

# promote sp1 data to SoilProfileCollection
depths(sp1) <- id ~ top + bottom

# move site data
site(sp1) <- ~ group

# compute indices
# merged into `sp1` with left-join on hzidname(sp1)
horizons(sp1) <- horizonColorIndices(sp1, hue="hue", value="value", chroma="chroma")

# visualize
par(mar=c(0, 1, 3, 1))
plot(sp1, color='hurst_redness')
plot(sp1, color='barron_torrent_redness')
plot(sp1, color='buntley_westin')
```

---

```
horizonDepths<-      Set horizon depth column names
```

---

**Description**

Set column name containing horizon ID

Get column names containing horizon depths

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection'
horizonDepths(object) <- value
```

```
## S4 method for signature 'SoilProfileCollection'
horizonDepths(object)
```

**Arguments**

object	a SoilProfileCollection
value	a character vector of length two with names of columns containing numeric top and bottom depths

---

```
horizonNames<-      Set horizon column names
```

---

**Description**

Set horizon column names

Get names of columns in horizon table.

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection'
horizonNames(object) <- value
```

```
## S4 method for signature 'SoilProfileCollection'
horizonNames(object)
```

**Arguments**

object	a SoilProfileCollection
value	a unique vector of equal length to number of columns in horizons length(horizonNames(object))

---

horizons, SoilProfileCollection-method

*Retrieve horizon data from SoilProfileCollection*

---

### Description

Get horizon data from SoilProfileCollection. Result is returned in the same data.frame class used to initially construct the SoilProfileCollection.

Horizon data in an object inheriting from data.frame can easily be added via merge (LEFT JOIN). There must be one or more same-named columns (with at least some matching data) on the left and right hand side to facilitate the join: horizons(spc) <- newdata

### Usage

```
## S4 method for signature 'SoilProfileCollection'
horizons(object)

## S4 replacement method for signature 'SoilProfileCollection'
horizons(object) <- value
```

### Arguments

object	A SoilProfileCollection
value	An object inheriting data.frame

### Examples

```
# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# assign true to surface horizon
newdata <- data.frame(top = 0,
                      newvalue = TRUE)

# do left join
horizons(sp2) <- newdata

# inspect site table: newvalue TRUE only for horizons
# with top depth equal to zero
horizons(sp2)
```

---

`huePosition`*Munsell Hue Reference and Position Searching*

---

**Description**

The 40 Munsell hues are typically arranged from 5R to 2.5R moving clock wise on the unit circle. This function matches a vector of hues to positions on that circle, with options for setting a custom origin or search direction.

This function is fully vectorized.

**Usage**

```
huePosition(  
  x,  
  returnHues = FALSE,  
  includeNeutral = FALSE,  
  origin = "5R",  
  direction = c("cw", "ccw")  
)
```

**Arguments**

<code>x</code>	character vector of hues, e.g. <code>c('10YR', '5YR')</code> , optional if <code>returnHues = TRUE</code>
<code>returnHues</code>	logical, should the full set of Munsell hues be returned? See details.
<code>includeNeutral</code>	logical, add 'N' to the end of the full set of Munsell hues
<code>origin</code>	hue to be used as the starting point for position searches (position 1)
<code>direction</code>	indexing direction, should be <code>cw</code> (clock wise) or <code>ccw</code> (counter-clock wise)

**Value**

A vector of integer hue positions is returned, of the same length and order as `x`. If `returnHues = TRUE`, then all hue names and ordering are returned and `x` is ignored.

**Author(s)**

D.E. Beaudette

**References**

- Soil Survey Technical Note 2 [wayback machine URL](#)
- Munsell book of color. 1976. Macbeth, a Division of Kollmorgen Corp., Baltimore, MD.

**See Also**

[colorContrast](#), [huePositionCircle](#)

**Examples**

```

# get hue ordering for setting levels of a factor
huePosition(returnHues = TRUE)

# get hue ordering including N (neutral)
huePosition(returnHues = TRUE, includeNeutral = TRUE)

# get position of the '10YR' hue, relative to standard origin of '5R'
# should be 7
huePosition(x = '10YR')

# get position of the '10YR' hue, relative to standard origin of '5YR'
# should be 3
huePosition(x = '10YR', origin = '5YR')

# visualize
op <- par(mar = c(0, 0, 0, 0), fg = 'white', bg = 'black')

huePositionCircle(huePosition(returnHues = TRUE, origin = '5YR'))

par(op)

```

---

huePositionCircle      *Visual Description of Munsell Hue Ordering*

---

**Description**

Munsell hues are arranged on the unit circle with "neutral" at the center.

**Usage**

```

huePositionCircle(
  hues = huePosition(returnHues = TRUE),
  value = 6,
  chroma = 10,
  chip.cex = 5.5,
  label.cex = 0.66,
  seg.adj = 0.8,
  seg.col = "grey",
  plot = TRUE,
  simulateCVD = NULL,
  CVDseverity = 1
)

```

**Arguments**

hues	vector of Munsell hues, commonly derived from <code>huePosition()</code>
value	single integer, Munsell value used to create an actual color
chroma	single integer, Munsell chroma used to create an actual color
chip.cex	numeric, scaling for color chips
label.cex	numeric, scaling labels
seg.adj	numeric, scaling for line segment cues
seg.col	single color, color used for line segment cues
plot	logical, generate output on the current graphics device
simulateCVD	simulate color vision deficiencies with the <code>colspace</code> package, should be the character representation of a function name, one of: 'deutan', 'protan', or 'tritan'.
CVDseverity	numeric value between 0 (none) and 1 (total), describing the severity of the color vision deficiency

**Value**

an invisible `data.frame` of data used to create the figure

**Note**

The best results are obtained when setting margins to zero, and inverting foreground / background colors. For example: `par(mar = c(0, 0, 0, 0), fg = 'white', bg = 'black')`.

**References**

Munsell book of color. 1976. Macbeth, a Division of Kollmorgen Corp., Baltimore, MD.

**Examples**

```
# keep examples from using more than 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

# better graphics defaults
op <- par(mar = c(0, 0, 0, 0), fg = 'white', bg = 'black')

# full set of hues, as generated by huePosition(returnHues = TRUE)
huePositionCircle()

# subset
huePositionCircle(hues = c('5R', '5Y', '5G', '5B', '5P'))

# reset graphics state
par(op)
```

---

hurst.redness	<i>Hurst (1977) Redness Index</i>
---------------	-----------------------------------

---

**Description**

Calculate Redness Index after Hurst (1977) "Visual estimation of iron in saprolite" DOI: 10.1130/0016-7606(1977)88<174:VEOIS>2.0.CO;2. Accepts vectorized inputs for hue, value and chroma, produces vector output.

**Usage**

```
hurst.redness(hue, value, chroma)
```

**Arguments**

hue	A character vector containing Munsell hues (e.g. "7.5YR")
value	A numeric vector containing Munsell values
chroma	A numeric vector containing Munsell chromas

**Value**

A numeric vector of horizon redness index (lower values = redder).

**Author(s)**

Andrew G. Brown

**References**

Hurst, V.J. (1977) Visual estimation of iron in saprolite. GSA Bulletin. 88(2): 174–176. doi: [https://doi.org/10.1130/0016-7606\(1977\)88<174:VEOIS>2.0.CO;2](https://doi.org/10.1130/0016-7606(1977)88<174:VEOIS>2.0.CO;2)

---

hzAbove	<i>Horizons Above or Below</i>
---------	--------------------------------

---

**Description**

Horizons Above or Below

**Usage**

```
hzAbove(x, ..., offset = 1, SPC = TRUE, simplify = SPC)
```

```
hzBelow(x, ..., offset = 1, SPC = TRUE, simplify = SPC)
```

```
hzOffset(x, hzid, offset, SPC = FALSE, simplify = TRUE)
```

**Arguments**

x	A SoilProfileCollection
...	Comma-separated set of R expressions that evaluate as TRUE or FALSE in context of horizon data frame. Length for individual expressions matches number of horizons, in x.
offset	Integer offset in terms of SoilProfileCollection [, j] (horizon/slice) index
SPC	Return a SoilProfileCollection? Default TRUE for horizon_* methods.
simplify	If TRUE return a vector (all elements combined), or a list (1 element per profile). If SPC is TRUE then simplify is TRUE.
hzid	A vector of target horizon IDs. These are calculated from ... for horizon_*() methods

**Details**

To minimize likelihood of issues with non-standard evaluation context, especially when using hzAbove()/hzBelow() inside another function, all expressions used in ... should be in terms of variables that are in the horizon data frame.

**Value**

A SoilProfileCollection (when SPC = TRUE) or a vector of horizon row indices (when SPC = FALSE and simplify = TRUE) or a list (when SPC = FALSE and simplify = FALSE))

**Examples**

```
data(sp4)
depths(sp4) <- id ~ top + bottom

# get the horizon above the last horizon (j-index of bottom horizon minus 1)
hzAbove(sp4, hzID(sp4) %in% getLastHorizonID(sp4))

# get horizons below the last horizon (none; j-index of bottom horizon plus 1)
hzBelow(sp4, hzID(sp4) %in% getLastHorizonID(sp4))
```

---

HzDepthLogicSubset     *Subset* SoilProfileCollection   *Objects or Horizons* via  
checkHzDepthLogic

---

**Description**

This function removes profiles or horizons from a SoilProfileCollection that are flagged as having invalid horizon depth logic by [checkHzDepthLogic](#). Invalid profiles may be created when setting byhz = TRUE; use caution as some functions may not work properly in the presence of gaps. Consider using [fillHzGaps](#) to fill these gaps.

**Usage**

```
HzDepthLogicSubset(x, byhz = FALSE)
```

**Arguments**

x                    a SoilProfileCollection object  
 byhz                logical, evaluate horizon depth logic at the horizon level (profile level if FALSE)

**Value**

a SoilProfileCollection object

**Note**

This function cannot identify (and remove) overlapping horizons when byhz = TRUE.

---

hzDepthTests	<i>Tests of horizon depth logic</i>
--------------	-------------------------------------

---

**Description**

Function used internally by checkHzDepthLogic(), glom() and various other functions that operate on horizon data from single soil profiles and require a priori depth logic checks. Checks for bottom depths less than top depth / bad top depth order ("depthLogic"), bottom depths equal to top depth ("sameDepth"), overlaps/gaps ("overlapOrGap") and missing depths ("missingDepth"). Use names(res)[res] on result res of hzDepthTest() to determine type of logic error(s) found – see examples below.

**Usage**

```
hzDepthTests(top, bottom = NULL)
```

**Arguments**

top                    A numeric vector containing horizon top depths. Or a data.frame with two columns (first containing top depths, second containing bottom)  
 bottom                A numeric vector containing horizon bottom depths.

**Value**

A named logical vector containing TRUE for each type of horizon logic error found in the given data.

**Author(s)**

Andrew G. Brown & Dylan E. Beaudette

**Examples**

```
# no logic errors
res <- hzDepthTests(top = c(0,10,20,30), bottom = c(10,20,30,50))
names(res)[res]

# bottom < top
hzDepthTests(top = c(10,20,30,50), bottom = c(0,10,20,30))
names(res)[res]

hzDesgn,SoilProfileCollection-method

*Get horizon designation column name*

---

**Description**

Get horizon designation names

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
hzDesgn(object)
```

**Arguments**

object            a SoilProfileCollection

---

hzdesgname	<i>Get or Set Horizon Designation Column Name</i>
------------	---

---

**Description**

hzdesgname(): Get column name containing horizon designations  
hzdesgname<-: Set horizon designation column name

**Usage**

```
## S4 method for signature 'SoilProfileCollection'  
hzdesgname(object, required = FALSE)  
  
## S4 replacement method for signature 'SoilProfileCollection'  
hzdesgname(object, required = FALSE) <- value
```

**Arguments**

object	a SoilProfileCollection
required	logical, is this attribute required? If it is, set to TRUE to trigger error on invalid value.
value	character, name of column containing horizon designations

**Details**

Store the column name containing horizon designations or other identifiers in the metadata slot of the SoilProfileCollection.

**See Also**

[hzDesgn\(\)](#)

**Examples**

```
data(sp1)  
  
# promote to SPC  
depths(sp1) <- id ~ top + bottom  
  
# set horizon designation column  
hzdesgname(sp1) <- "name"  
  
# get horizon designation column  
hzdesgname(sp1)
```

---

```
hzDistinctnessCodeToOffset
```

*Convert Horizon Boundary Distinctness to Vertical Offset*

---

### Description

This function will convert USDA-NCSS horizon boundary distinctness codes into vertical (+/-) offsets in cm, based on the [Field Book for Describing and Sampling Soils, version 3.0](#).

### Usage

```
hzDistinctnessCodeToOffset(
  x,
  codes = c("very abrupt", "abrupt", "clear", "gradual", "diffuse"),
  offset = c(0.5, 2, 5, 15, 20)/2
)
```

### Arguments

x	vector of boundary distinctness codes to be converted
codes	character vector of distinctness terms ('clear') or codes ('C'), case insensitive, see details
offset	vertical offset factors (cm), approximating 1/2 of the transitional zone thickness, see details

### Details

The default offsets are based on the high-end of ranges presented in "transitional zone thickness criteria" from the Field Book version 3.0 (page 2-6). Offsets are returned as 1/2 of the transitional zone thickness so that horizon boundaries can be adjusted up/down from horizon depths. See [plotSPC](#), specifically the `hz.distinctness.offset` argument for visualization ideas. Missing data in x (NA) or codes that are not defined in codes are returned as 0 offsets.

Either format (or mixture) are accepted, case insensitive:

- terms: `c('very abrupt', 'abrupt', 'clear', 'gradual', 'diffuse')`
- coded values: `c('v', 'a', 'c', 'g', 'd')`

Additional examples are available in the [Visualization of Horizon Boundaries tutorial](#).

### Value

vector of offsets with same length as x

### Author(s)

D.E. Beaudette

**References**

[Field Book for Describing and Sampling Soils, version 3.0](#)

**See Also**

[plotSPC](#)

**Examples**

```
# example data
data(sp1)

# compute 1/2 transitional zone thickness from distinctness codes
sp1$hzdo <- hzDistinctnessCodeToOffset(sp1$bound_distinct)

# convert colors from Munsell to hex-encoded RGB
sp1$soil_color <- with(sp1, munsell2rgb(hue, value, chroma))

# promote to SoilProfileCollection
depths(sp1) <- id ~ top + bottom
hzdesgname(sp1) <- 'name'

# adjust margins
op <- par(mar=c(0,0,0,1.5))

# sketches, adjust width, adjust text size, include coded hz distinctness offsets
plotSPC(sp1, width=0.3, cex.names=0.75, hz.distinctness.offset = 'hzdo')

# clean-up
par(op)
```

---

```
hzID<- ,SoilProfileCollection-method
  Set horizon IDs
```

---

**Description**

Set vector containing horizon IDs

Get vector containing horizon IDs

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection'
hzID(object) <- value

## S4 method for signature 'SoilProfileCollection'
hzID(object)
```

**Arguments**

object	a SoilProfileCollection
value	a unique vector of equal length to number of horizons nrow(object)

---

hzigname<-	<i>Set horizon ID column name</i>
------------	-----------------------------------

---

**Description**

Set unique horizon ID column name

Get column name containing unique horizon ID

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection'
hzigname(object) <- value
```

```
## S4 method for signature 'SoilProfileCollection'
hzigname(object)
```

**Arguments**

object	a SoilProfileCollection
value	character, column name containing unique horizon ID values

**Examples**

```
data(sp1)

# promote to SPC
depths(sp1) <- id ~ top + bottom

# create new horizon ID
sp1$hzigIDrev <- rev(sp1$hzigID)

# set horizon designation column
hzigname(sp1) <- "hzigIDrev"

# get horizon designation column
hzigname(sp1)
```

---

hzMetadata,SoilProfileCollection-method  
*Get horizon-level metadata*

---

**Description**

Get idname(object) and hzidname(object), with hzdesgnname(object), hztexclname(object) (if defined)

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
hzMetadata(object)
```

**Arguments**

object            a SoilProfileCollection

---

hztexclname            *Get or Set Horizon Texture Class Column Name*

---

**Description**

hztexclname(): Get column name containing horizon designation name  
hztexclname<-: Set horizon texture class column name for a SoilProfileCollection

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
hztexclname(object, required = FALSE)

## S4 replacement method for signature 'SoilProfileCollection'
hztexclname(object, required = FALSE) <- value
```

**Arguments**

object            a SoilProfileCollection  
required           logical, is this attribute required? If it is, set to TRUE to trigger error on invalid value.  
value             character, name of column containing horizon texture classes

**Details**

Store the column name containing horizon texture classes or other identifiers in the metadata slot of the SoilProfileCollection.

**Examples**

```

data(sp1)

# promote to SPC
depths(sp1) <- id ~ top + bottom

# set horizon texture class column
hztexclname(sp1) <- "texture"

# get horizon texture class column
hztexclname(sp1)

```

---

```
hzTopographyCodeToLineType
```

*Convert Horizon Boundary Topography to Line Type*

---

**Description**

This function will convert USDA-NCSS horizon boundary topography codes into line types, based on the [Field Book for Describing and Sampling Soils, version 3.0](#).

**Usage**

```

hzTopographyCodeToLineType(
  x,
  codes = c("smooth", "wavy", "irregular", "broken"),
  lty = c(1, 2, 3, 4)
)

```

**Arguments**

x	vector of boundary topography codes to be converted
codes	character vector of topography terms ('smooth') or codes ('S'), case insensitive, see details
lty	line types

**Details**

Visualization of horizon boundary topography can be difficult, line type offers an additional visual cue. See `hzTopographyCodeToOffset` for an offset-based approach. Additional examples are available in the [Visualization of Horizon Boundaries tutorial](#). Missing data in x (NA) or codes that are not defined in codes are returned as line type 1.

Either format (or mixture) are accepted, case insensitive:

- terms: `c('smooth', 'wavy', 'irregular', 'broken')`
- coded values: `c('s', 'w', 'i', 'b')`

**Value**

vector of line types with same length as x

**Author(s)**

D.E. Beaudette

**References**

[plotSPC](#), [hzTopographyCodeToOffset](#)

---

hzTopographyCodeToOffset

*Convert Horizon Boundary Topography to Vertical Offset*

---

**Description**

This function will convert USDA-NCSS horizon boundary topography codes into a vertical offset, suitable for use in `plotSPC`. Default values are reasonable starting points for encoding smooth, wavy, irregular, or broken style horizon boundary topography as defined in [Field Book for Describing and Sampling Soils, version 3.0](#).

**Usage**

```
hzTopographyCodeToOffset(  
  x,  
  codes = c("smooth", "wavy", "irregular", "broken"),  
  offset = c(0, 4, 8, 12)  
)
```

**Arguments**

x	vector of boundary topography codes to be converted
codes	character vector of topography terms ('smooth') or codes ('S'), case insensitive, see details
offset	vertical offset (depth units) used to create "chevron" effect

**Details**

Additional examples are available in the [Visualization of Horizon Boundaries tutorial](#). Missing data in x (NA) or codes that are not defined in codes are returned with an offset of 0.

Either format (or mixture) are accepted, case insensitive:

- terms: `c('smooth', 'wavy', 'irregular', 'broken')`
- coded values: `c('s', 'w', 'i', 'b')`

**Value**

vector of vertical offsets with same length as x

**Author(s)**

D.E. Beaudette

**References**

[plotSPC](#)

---

hzTransitionProbabilities

*Horizon Transition Probabilities*

---

**Description**

Functions for creating and working with horizon (sequence) transition probability matrices.

See the following tutorials for some ideas:

- [horizon designation TP](#)
- [soil color TP](#)

**Usage**

```
hzTransitionProbabilities(
  x,
  name = GH(x, required = TRUE),
  loopTerminalStates = FALSE
)
```

```
mostLikelyHzSequence(mc, t0, maxIterations = 10)
```

**Arguments**

x	a SoilProfileCollection object.
name	A horizon level attribute in x that names horizons.
loopTerminalStates	should terminal states loop back to themselves? This is useful when the transition probability matrix will be used to initialize a markovchain object. See examples below.
mc	Passed to markovchain conditionalDistribution()
t0	Passed to markovchain conditionalDistribution()
maxIterations	Maximum number of iterations. Default: 10

**Value**

A square matrix of transition probabilities. See examples.

The function `genhzTableToAdjMat()` returns a square adjacency matrix. See examples.

The function `mostLikelyHzSequence()` returns the most likely sequence of horizons, given a markovchain object initialized from horizon transition probabilities and an initial state, `t0`. See examples.

**Note**

These functions are still experimental and subject to change.

**Author(s)**

D.E. Beaudette

**See Also**

[generalize.hz\(\)](#)

**Examples**

```
data(sp4)
depths(sp4) <- id ~ top + bottom

# horizon transition probabilities: row -> col transitions
(tp <- hzTransitionProbabilities(sp4, 'name'))

## Not run:
## plot TP matrix with functions from sharpshootR package
library(sharpshootR)
par(mar=c(0,0,0,0), mfcol=c(1,2))
plot(sp4)
plotSoilRelationGraph(tp, graph.mode = 'directed', edge.arrow.size=0.5)

## demonstrate genhzTableToAdjMat usage
data(loafercreek, package='soilDB')

# convert contingency table -> adj matrix / TP matrix
tab <- table(loafercreek$hzname, loafercreek$genhz)
m <- genhzTableToAdjMat(tab)

# plot
par(mar=c(0,0,0,0), mfcol=c(1,1))
plotSoilRelationGraph(m, graph.mode = 'directed', edge.arrow.size=0.5)

## demonstrate markovchain integration
library(markovchain)
tp.loops <- hzTransitionProbabilities(sp4, 'name', loopTerminalStates = TRUE)
```

```

# init new markovchain from TP matrix
mc <- new("markovchain", states=dimnames(tp.loops)[[1]], transitionMatrix = tp.loops)

# simple plot
plot(mc, edge.arrow.size=0.5)

# check absorbing states
absorbingStates(mc)

# steady-state:
steadyStates(mc)

## End(Not run)

```

---

```

idname, SoilProfileCollection-method
      Get profile ID column name

```

---

**Description**

Get column name containing unique profile IDs

**Usage**

```

## S4 method for signature 'SoilProfileCollection'
idname(object)

```

**Arguments**

object            a SoilProfileCollection

---

```

initSpatial<-            Initialize Spatial Data in a SoilProfileCollection

```

---

**Description**

`initSpatial()<-`: Set the column names containing spatial data and the corresponding coordinate reference system for a SoilProfileCollection.

`getSpatial()`: Get spatial data associated with a SoilProfileCollection

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection,ANY,ANY'  
initSpatial(object, crs = NULL) <- value  
  
## S4 replacement method for signature 'SoilProfileCollection,ANY,character'  
initSpatial(object, crs = NULL) <- value  
  
## S4 method for signature 'SoilProfileCollection'  
getSpatial(object)  
  
## S4 method for signature 'SoilProfileCollection'  
coordinates(obj)  
  
## S4 replacement method for signature 'SoilProfileCollection,ANY'  
coordinates(object) <- value  
  
## S4 replacement method for signature 'SoilProfileCollection,character'  
coordinates(object) <- value
```

**Arguments**

object	A SoilProfileCollection
crs	Optional: character. Representation of Coordinate Reference System as "authority:code", integer EPSG code, WKT2019 or PROJ4 string, an sf crs or sp CRS object.
value	A formula specifying names of columns containing geometry (x and y coordinates), or character with the column names
obj	A SoilProfileCollection

**See Also**

[prj\(\)](#)

**Examples**

```
data(sp5)  
  
# coordinates are stored in x and y column of site  
sp5$x <- rnorm(length(sp5))  
sp5$y <- rnorm(length(sp5))  
  
# coordinates takes a formula object as input  
initSpatial(sp5) <- ~ x + y  
  
# optionally specify Coordinate Reference System (crs) on left-hand side  
initSpatial(sp5, crs = "OGC:CRS84") <- ~ x + y
```

---

<code>invertLabelColor</code>	<i>Make High Contrast Label Colors</i>
-------------------------------	--

---

**Description**

Generate a vector of white or black label colors conditioned on a vector of colors to maximize label contrast.

**Usage**

```
invertLabelColor(colors, threshold = 0.65)
```

**Arguments**

<code>colors</code>	vector of colors
<code>threshold</code>	black   white threshold

**Value**

vector of label colors

**Author(s)**

D.E. Beaudette

**Examples**

```
# test with shades of grey
s <- seq(0, 1, by = 0.05)
cols <- grey(s)
soilPalette(cols, lab = as.character(s))

# test with 10YR x/3
m <- sprintf('10YR %s/3', 1:8)
cols <- parseMunsell(m)
soilPalette(cols, lab = m)
```

---

 isEmpty,SoilProfileCollection-method

*Check for "empty" profiles in a SoilProfileCollection*

---

### Description

"Empty" profiles are used as placeholders for positions in a SoilProfileCollection. These profiles result from operations that remove or extract portions of horizons from source profiles.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
isEmpty(object, ...)
```

### Arguments

object	A SoilProfileCollection
...	Additional arguments not used.

### Details

In a SoilProfileCollection an empty profile occurs when it has one horizon, with NA top and bottom depths. Generally all non-profile ID site and horizon-level values are all also NA, but only the depths are checked by isEmpty().

### Value

logical. Vector of length equal to number of profiles in object. Returns TRUE when a profile has one horizon with NA top and bottom depths

---

 jacobs2000

*Soil Morphologic Data from Jacobs et al. 2002.*

---

### Description

Select soil morphologic data from "Redoximorphic Features as Indicators of Seasonal Saturation, Lowndes County, Georgia". This is a useful sample dataset for testing the analysis and visualization of redoximorphic features.

### Usage

```
data(jacobs2000)
```

### Format

A SoilProfileCollection object.

## References

colorContrastPlot(cc$m1[11:21], cc$m2[11:21], labels = c('matrix', 'concentration'))

# color contrast: depletion vs. concentrations
cc <- colorContrast(jacobs2000$depletion_munsell, jacobs2000$concentration_munsell)
cc <- na.omit(cc)

cc <- cc[order(cc$dE00), ]
cc <- unique(cc)

par(bg='black', fg='white')
colorContrastPlot(cc$m1, cc$m2, labels = c('depletion', 'concentration'))
```

## Description

The L1 estimator, or **geometric median**, is a multivariate generalization of the (univariate) **median** concept. This function performs a multivariate aggregation (via L1 estimator) according to a suite of ratio-scale soil properties. The L1 estimator is applied to soil profile data that have been sliced to a 1-depth-unit basis. Data should be well stratified by groups defined in `fm`, otherwise the L1 median may not make any sense.

See the [L1 Profiles Tutorial](#) for additional examples.

## Usage

```
L1_profiles(
  x,
  fm,
  basis = 1,
  method = c("regex", "simple", "constant"),
  maxDepthRule = c("max", "min"),
  maxDepthConstant = NULL
)
```

## Arguments

<code>x</code>	SoilProfileCollection object
<code>fm</code>	formula, for example: <code>group ~ p1 + p2 + p3</code> , where "group" is a site-level grouping variable, and "p1", "p2", and "p3" are horizon level variables
<code>basis</code>	positive integer, aggregation basis (e.g. 1 for 1-depth-unit intervals). Values other than 1 are not currently supported.
<code>method</code>	soil depth evaluation method: "regex" for regular expression, "simple", or "constant". See details.
<code>maxDepthRule</code>	maximum depth rule: "max" or "min" See details.
<code>maxDepthConstant</code>	positive integer, maximum depth when <code>maxDepthRule = 'constant'</code>

## Details

See [this related tutorial](#) for additional examples. The `method`, `maxDepthRule`, and `maxDepthConstant` arguments set the maximum depth (over the entire collection) of analysis used to build "L1 profiles". The following rules are available:

- `method = 'regex'` uses pattern matching on horizon designations (note that `hzdesgnname` metadata must be set with `hzdesgnname(x) <- 'columnname'`)
- `method = 'simple'` uses min or max as applied to `x`, no accounting for non-soil horizons (e.g. Cr or R)

- `method = 'constant'` uses a fixed depth value supplied by `maxDepthConstant`

The `maxDepthRule` argument sets depth calculation constraint, applied to soil depths computed according to `method` (min or max).

**Value**

a `SoilProfileCollection` object

**Note**

This function requires the `Gmedian` package.

**References**

Cardot, H., Cenac, P. and Zitt, P-A. (2013). Efficient and fast estimation of the geometric median in Hilbert spaces with an averaged stochastic gradient algorithm. *Bernoulli*, 19, 18-43.

---

`length,SoilProfileCollection-method`

*Get the number of profiles in a `SoilProfileCollection`*

---

**Description**

Get the number of profiles in a `SoilProfileCollection`

**Usage**

```
## S4 method for signature 'SoilProfileCollection'  
length(x)
```

**Arguments**

`x` a `SoilProfileCollection`

---

lunique	<i>Eliminate duplicate instances of profile IDs in a list of SoilProfileCollections</i>
---------	---

---

### Description

@description Experimental function to "clean" list input where duplicates exist (that would otherwise prevent pbindlist). Useful for queries that may have overlapping instances of the same data, for instance a list of SoilProfileCollections where each list element contains profiles gathered from a set of (potentially overlapping) extents.

### Usage

```
lunique(l)
```

### Arguments

l                    A list of SoilProfileCollections.

### Value

A list of SoilProfileCollections, with duplicate profile IDs removed.

### Author(s)

Andrew G. Brown

### Examples

```
data(sp5)

# EXAMPLE #1 -- resolving overlap

# 6 profiles in four sets, and 5,6,7 are missing
input <- lapply(list(c(1,3,4), c(2,2,3), NA, c(8,9,1)), function(idx) {
  if(!all(is.na(idx)))
    sp5[idx,]
})

output <- lunique(input)

# 6 profiles are in final SPC; 5,6,7 are missing
match(profile_id(pbindlist(output)), profile_id(sp5))

# EXAMPLE #2 -- exact duplicates

# deliberately duplicate an SPC
sp5_2 <- sp5
```

```
res <- lunique(list(sp5, sp5_2))

# the number of profiles in first element is equal to number in sp5
length(res[[1]]) == length(sp5)

# second list element contains NA b/c all uniques are in #1
res[[2]]
```

---

```
max,SoilProfileCollection-method
```

*Get the maximum bottom depth in a SoilProfileCollection*

---

### Description

Get the deepest depth of description out of all profiles in a SoilProfileCollection. Data missing one or more of: bottom depth, profile ID, or any optional attribute are omitted using `complete.cases`.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
max(x, v = NULL, na.rm = TRUE)
```

### Arguments

<code>x</code>	a SoilProfileCollection
<code>v</code>	optional: horizon-level column name to refine calculation
<code>na.rm</code>	remove NA? default: TRUE

---

```
metadata,SoilProfileCollection-method
```

*Retrieve metadata from SoilProfileCollection*

---

### Description

Get metadata from SoilProfileCollection. Result is a list. Two entries (`aqp_df_class`, `depth_units`) should not be edited in the metadata list directly. There are methods that facilitate changing them – and propagating their changes throughout the collection. Otherwise, metadata list is a free-form slot used to store arbitrary information about the data, how it was collected, citations, etc.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
metadata(object)

## S4 replacement method for signature 'SoilProfileCollection'
metadata(object) <- value
```

**Arguments**

object	A SoilProfileCollection
value	A named list (see examples)

**Examples**

```
data(sp5)

# replace default metadata with itself
metadata(sp5) <- metadata(sp5)

# set new metadata attribute value
metadata(sp5)$newvalue <- 'foo'

# get metadata attribute
metadata(sp5)$newvalue
```

---

min,SoilProfileCollection-method

*Get the minimum bottom depth in a SoilProfileCollection*

---

**Description**

Get the shallowest depth of description out of all profiles in a SoilProfileCollection. Data missing one or more of: bottom depth, profile ID, or any optional attribute are omitted using `complete.cases`.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
min(x, v = NULL, na.rm = TRUE)
```

**Arguments**

x	a SoilProfileCollection
v	optional: a vector of horizon attribute names to refine calculation
na.rm	remove NA? default: TRUE

---

missingDataGrid	<i>Missing Data Grid</i>
-----------------	--------------------------

---

**Description**

Generate a levelplot of missing data from a SoilProfileCollection object.

**Usage**

```
missingDataGrid(  
  s,  
  max_depth,  
  vars,  
  filter.column = NULL,  
  filter.regex = NULL,  
  cols = NULL,  
  ...  
)
```

**Arguments**

s	a SoilProfileCollection object
max_depth	integer specifying the max depth of analysis
vars	character vector of column names over which to evaluate missing data
filter.column	a character string naming the column to apply the filter REGEX to
filter.regex	a character string with a regular expression used to filter horizon data OUT of the analysis
cols	a vector of colors
...	additional arguments passed on to levelplot

**Details**

This function evaluates a missing data fraction based on slice-wise evaluation of named variables in a SoilProfileCollection object.

**Value**

A data.frame describing the percentage of missing data by variable.

**Note**

A lattice graphic is printed to the active output device.

**Author(s)**

D.E. Beaudette

**See Also**[slice](#)**Examples**

```

# 10 random profiles
set.seed(10101)
s <- lapply(as.character(1:10), random_profile)
s <- do.call('rbind', s)

# randomly sprinkle some missing data
s[sample(nrow(s), 5), 'p1'] <- NA
s[sample(nrow(s), 5), 'p2'] <- NA
s[sample(nrow(s), 5), 'p3'] <- NA

# set all p4 and p5 attributes of `soil 1' to NA
s[which(s$id == '1'), 'p5'] <- NA
s[which(s$id == '1'), 'p4'] <- NA

# upgrade to SPC
depths(s) <- id ~ top + bottom

# plot missing data via slicing + levelplot
missingDataGrid(
  s,
  max_depth = 100,
  vars = c('p1', 'p2', 'p3', 'p4', 'p5'),
  main='Missing Data Fraction'
)

```

---

mixMunsell

*Mix Munsell Colors via Spectral Library*

---

**Description**

Simulate mixing of colors in Munsell notation, similar to the way in which mixtures of pigments operate.

**Usage**

```

mixMunsell(
  x,
  w = rep(1, times = length(x))/length(x),
  mixingMethod = c("exact", "reference", "estimate", "adaptive"),
  n = 1,
  keepMixedSpec = FALSE,
  distThreshold = 0.025,

```

```
    ...
  )
```

### Arguments

x	vector of colors in Munsell notation
w	vector of proportions, can sum to any number
mixingMethod	approach used to simulate a mixture: <ul style="list-style-type: none"> <li>• exact: simulate a subtractive mixture of pigments, color conversion via CIE1931 color-matching functions (see details)</li> <li>• reference: simulate a subtractive mixture of pigments, selecting n closest reference spectra from <code>munsell.spectra.wide</code> (requires gower package)</li> <li>• estimate: closest Munsell chip to a weighted mean of CIELAB coordinates (fastest)</li> <li>• adaptive: use exact method when possible, falling-back to estimate (weighted mean of CIELAB coordinates) otherwise</li> </ul>
n	number of closest matching color chips (mixingMethod = reference only)
keepMixedSpec	keep weighted geometric mean spectra, final result is a list (mixingMethod = reference only)
distThreshold	spectral distance used to compute scaledDistance, default value is based on an analysis of spectral distances associated with adjacent Munsell color chips. This argument is only used with mixingMethod = 'reference'.
...	additional arguments to <code>spec2Munsell</code>

### Details

See the [expanded tutorial](#) for examples.

An accurate simulation of pigment mixtures ("subtractive" color mixtures) is incredibly complex due to factors that aren't easily measured or controlled: pigment solubility, pigment particle size distribution, water content, substrate composition, and physical obstruction to name a few. That said, it is possible to simulate reasonable, subtractive color mixtures given a reference spectra library (350-800nm) and some assumptions about pigment qualities and lighting. For the purposes of estimating a mixture of soil colors (these are pigments after all) we can relax these assumptions and assume a standard light source. The only missing piece is the spectral library for all Munsell chips in our color books.

Thankfully, [Scott Burns has outlined the entire process](#), and Paul Centore has provided a Munsell color chip [reflectance spectra library](#). The estimation of a subtractive mixture of soil colors can proceed as follows:

1. look up the associated spectra for each color in x
2. compute the weighted (w argument) geometric mean of the spectra
3. convert the spectral mixture to the closest Munsell color via:
  - search for the closest n matching spectra in the reference library (mixtureMethod = 'reference')
  - direct conversion of spectra to closest Munsell color via `spec2Munsell()` (mixtureMethod = 'exact')

1. suggest resulting Munsell chip(s) as the best candidate for a simulated mixture

Key assumptions include:

- similar particle size distribution
- similar mineralogy (i.e. pigmentation qualities)
- similar water content.

For the purposes of estimating (for example) a "mixed soil color within the top 18cm of soil" these assumptions are usually valid. Again, these are estimates that are ultimately "snapped" to the nearest chip and do not need to approach the accuracy of paint-matching systems.

A message is printed when scaledDistance is larger than 1.

### Value

A data.frame with the closest matching Munsell color(s):

- munsell: Munsell notation of the n-closest spectra
- distance: spectral (Gower) distance to the n-closest spectra
- scaledDistance: spectral distance scaled by distThreshold
- mixingMethod: method used for each mixture

When keepMixedSpec = TRUE then a list:

- mixed: a data.frame containing the same elements as above
- spec: spectra for the 1st closest match

mollic.thickness.requirement
```

*Calculate the minimum thickness requirement for Mollic epipedon*

---

### Description

Utilize horizon depths, designations and textures in a profile to estimate the thickness requirement for the Mollic or Umbric epipedon, per criterion 6 in the U.S. Keys to Soil Taxonomy (12th Edition).

### Usage

```
mollic.thickness.requirement(
  p,
  hzdesgn = guessHzDesgnName(p),
  texcl.attr = guessHzTexClName(p),
  clay.attr = guessHzAttrName(p, "clay", c("total", "_r")),
  truncate = TRUE
)
```

### Arguments

<code>p</code>	A single-profile <code>SoilProfileCollection</code> .
<code>hzdesgn</code>	Column in horizon table containing designations. Default: <code>guessHzDesgnName(p)</code>
<code>texcl.attr</code>	Column in horizon table containing texture classes. Default: <code>guessHzTexClName(p)</code>
<code>clay.attr</code>	Column in horizon table containing clay contents. Default: <code>guessHzAttrName(p, 'clay', c('total', '_r'))</code>
<code>truncate</code>	Should sliding scale (Criterion 6C) results be truncated to 18 to 25cm interval? (Experimental; Default: TRUE)

### Value

A unit length numeric vector containing Mollic or Umbric epipedon minimum thickness requirement.

### Author(s)

Andrew G. Brown

### Examples

```
# construct a fake profile
spc <- data.frame(id=1, taxsubgrp = "Lithic Haploxeralfs",
  hzname = c("A", "AB", "Bt", "BCt", "R"),
  hzdept = c(0, 20, 32, 42, 49),
  hzdepb = c(20, 32, 42, 49, 200),
  prop = c(18, 22, 28, 24, NA),
  texcl = c("1", "1", "c1", "1", "br"),
```

```

      d_value = c(5, 5, 5, 6, NA),
      m_value = c(2.5, 3, 3, 4, NA),
      m_chroma = c(2, 3, 4, 4, NA))

# promote to SoilProfileCollection
depths(spc) <- id ~ hzdept + hzdepb
hzdesgname(spc) <- 'hzname'
hztexclname(spc) <- 'texcl'

# print results in table
data.frame(id = spc[[idname(spc)]],
           thickness_req = mollic.thickness.requirement(spc, clay.attr='prop'),
           thickness_req_nobound = mollic.thickness.requirement(spc,
                                                                clay.attr='prop', truncate=FALSE))

```

munsell

*Munsell to sRGB Lookup Table for Common Soil Colors*

---

## Description

A lookup table of interpolated Munsell color chips for common soil colors.

## Usage

```
data(munsell)
```

## Format

A data frame with 8825 rows.

**hue** Munsell Hue, upper case

**value** Munsell Value

**chroma** Munsell Chroma

**r** sRGB "red" value (0-1)

**g** sRGB "green" value (0-1)

**b** sRGB "blue" value (0-1)

**L** CIE LAB "L" coordinate

**A** CIE LAB "A" coordinate

**B** CIE LAB "B" coordinate

## Details

See `munsell2rgb` for conversion examples. Note that this table does not currently have entries for values of 2.5—common in most soil color books. These chips should be added in the next major release of `aqp`. Values are referenced to the D65 standard illuminant.

*Spectral Library of Munsell Colors*

---

**Description**

The original database "SpectralReflectancesOf2007MunsellBookOfColorGlossy.txt" was provided by Paul Centore and downloaded July, 2020. Reflectance values for odd chroma have been interpolated from adjacent chips. See `aqp/misc/utis/Munsell/` for the entire set of processing steps.

Munsell value typically ranges from 2-9, and chroma from 1-12. Ranges vary by hue. Run `aqp:::summarizeMunsellSpectraRanges()` for a detailed listing by hue.

The original database contains the following description:

This file contains spectral reflectance measurements of X-Rite's 2007 Munsell Book of Color (Glossy Finish). The measurements were made in 2012 with a ColorMunki spectrophotometer. The first column is the Munsell name. The remaining columns give reflectance values for 380 nm to 730 nm, in steps of 10 nm. The reflectance is a value between 0 (indicating that no light at that wavelength is reflected) and 1 (indicating that all the light at that wavelength is reflected). Occasionally an entry is slightly greater than 1. The likely cause is random variability, and those entries can be adjusted to 1 with negligible loss. In all, 1485 colour samples were measured. Researchers are invited to analyze the data in this file.

**Usage**

```
data(munsell.spectra)
```

**Format**

A data frame with 89496 rows and 10 variables:

**munsell** munsell color

**hue** hue component

**value** value component

**chroma** chroma component  
**wavelength** wavelength (nm)  
**reflectance** reflectance

---

munsell2rgb	<i>Convert Munsell Color Notation to other Color Space Coordinates (sRGB and CIELAB)</i>
-------------	--

---

## Description

Color conversion based on a look-up table of common soil colors.

## Usage

```
munsell2rgb(
  the_hue,
  the_value,
  the_chroma,
  alpha = 1,
  maxColorValue = 1,
  return_triplets = FALSE,
  returnLAB = FALSE
)
```

## Arguments

the_hue	a vector of one or more more hues, upper-case (e.g. '10YR')
the_value	a vector of one or more values (e.g. '4')
the_chroma	a vector of one or more chromas (e.g. '6'), may be NA for neutral hues
alpha	numeric, transparency setting used when return_triplets = FALSE and returnLAB = FALSE
maxColorValue	maximum sRGB color value, typically 1 (see <a href="#">rgb</a> )
return_triplets	logical, return sRGB coordinates (range 0-1) instead of standard hex notation of sRGB (e.g. '#8080B')
returnLAB	logical, return CIELAB coordinates (D65 illuminant)

**Details**

This function is vectorized without recycling: i.e. the length of each argument must be the same. Both functions will pad output with NA if there are any NA present in the inputs.

Neutral hues are approximated by greyscale shades ranging from 20\

Gley soil colors that are missing a chroma will not be correctly interpreted. Consider using a chroma of 1. Non-standard Munsell notation (e.g. '7.9YR 2.7/2.0') can be matched (nearest-neighbor, no interpolation) to the closest color within the munsell sRGB/CIELAB look-up table via `getClosestMunsellChip()`. A more accurate estimate of sRGB values from non-standard notation can be achieved with the [munsellinterpol](#) package.

See examples below.

**Value**

A vector of R colors is returned that is the same length as the input data. When `return_triplets = TRUE` and/or `returnLAB = TRUE`, then a data.frame (of sample length as input) is returned.

**Note**

Care should be taken when using the resulting sRGB values; they are close to their Munsell counterparts, but will vary based on your monitor and ambient lighting conditions. Also, the value used for `maxColorValue` will affect the brightness of the colors. The default value (1) will usually give acceptable results, but can be adjusted to force the colors closer to what the user thinks they should look like.

**Examples**

```
# neutral hues (N) can be defined with chroma of 0 or NA
g <- expand.grid(hue='N', value=2:8, chroma=0, stringsAsFactors=FALSE)
(m <- munsell2rgb(g$hue, g$value, g$chroma))
soilPalette(m)

# back-transform
rgb2munsell(t(col2rgb(m)) / 255)

# basic example
d <- expand.grid(hue='10YR', value=2:8, chroma=1:8, stringsAsFactors=FALSE)
d$color <- with(d, munsell2rgb(hue, value, chroma))
```

```

# similar to the 10YR color book page
plot(value ~ chroma, data=d, col=d$color, pch=15, cex=3)

# multiple pages of hue:
hues <- c('2.5YR', '5YR', '7.5YR', '10YR')
d <- expand.grid(hue=hues, value=c(2, 2.5, 3:8), chroma=seq(2,8,by=2), stringsAsFactors=FALSE)
# convert Munsell -> sRGB
d$color <- with(d, munsell2rgb(hue, value, chroma))

# extract CIELAB coordinates
with(d, munsell2rgb(hue, value, chroma, returnLAB=TRUE))

# plot: note that we are setting panel order from red --> yellow
library(lattice)
xyplot(value ~ factor(chroma) | factor(hue, levels=hues),
       main="Common Soil Colors", layout=c(4,1), scales=list(alternating=1),
       strip=strip.custom(bg=grey(0.85)),
       data=d, as.table=TRUE, subscripts=TRUE, xlab='Chroma', ylab='Value',
       panel=function(x, y, subscripts, ...)
       {
         panel.xyplot(x, y, pch=15, cex=4, col=d$color[subscripts])
       }
)

# soils example
data(sp1)

# convert colors
sp1$soil_color <- with(sp1, munsell2rgb(hue, value, chroma))

# simple plot, may need to tweak gamma-correction...
image(matrix(1:nrow(sp1)), axes=FALSE, col=sp1$soil_color, main='Soil Colors')

# convert into a more useful color space
# you will need the colorspace package for this to work
if(require(colorspace)) {
  # keep RGB triplets from conversion
  sp1.rgb <- with(sp1, munsell2rgb(hue, value, chroma, return_triplets=TRUE))

  # convert into LAB color space
  sp1.lab <- as(with(sp1.rgb, sRGB(r,g,b)), 'LAB')
  plot(sp1.lab)
}

# convert a non-standard color to closest "chip" in `munsell` look-up table
getClosestMunsellChip('7.9YR 2.7/2.0', convertColors = FALSE)
# convert directly to R color
getClosestMunsellChip('7.9YR 2.7/2.0')

```

---

 munsell2spc,SoilProfileCollection-method

*Merge Munsell Hue, Value, Chroma converted to sRGB & CIELAB into a SoilProfileCollection*

---

### Description

Convert Munsell hue, value and chroma into sRGB (rgb\_R, rgb\_G, rgb\_B) and CIELAB (lab\_L, lab\_A, lab\_B) color coordinates using `munsell2rgb`. The converted values are stored in the `horizons()` slot unless `as.spc` is FALSE, in which case the results are combined with profile and horizon ID columns and returned as the `data.frame` subclass used by the SPC.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
munsell2spc(
  object,
  hue = "hue",
  value = "value",
  chroma = "chroma",
  .data = NULL,
  as.spc = TRUE
)
```

### Arguments

<code>object</code>	A <code>SoilProfileCollection</code>
<code>hue</code>	Column name containing numeric hue values. Default: "hue"
<code>value</code>	Column name containing numeric value values. Default: "value"
<code>chroma</code>	Column name containing numeric chroma values. Default: "chroma"
<code>.data</code>	Optional: a character vector of equal length to number of horizons (containing Munsell notation), or a column name in the horizon data OR a <code>data.frame</code> containing three columns (names specified in hue, value, chroma)
<code>as.spc</code>	Return a <code>data.frame</code> -like object with ID columns?

### Value

A `SoilProfileCollection` or `data.frame`-like object

### See Also

[parseMunsell](#) [rgb2munsell](#) [munsell2rgb](#)

## Examples

```
data(sp3)
depths(sp3) <- id ~ top + bottom

# inspect input data
horizons(sp3)[,c("hue", "value", "chroma")]

# do color conversions to sRGB and LAB, join into horizon data
sp3 <- munsell2spc(sp3)

# plot rgb "R" coordinate by horizon
plot(sp3, color = "rgb_R")

# plot lab "A" coordinate by horizon
plot(sp3, color = "lab_A")

# note that `lab_A` values do not exactly match the original `A` values
# this is because `lab_A` was computed from the (field determined) Munsell color notation,
# while `A` was directly measured in the lab by colorimeter
plot(sp3$A, sp3$lab_A, xlab = 'Measured', ylab = 'Converted from Field Observed Munsell')
```

---

munsellHuePosition      *Munsell Hue Position Reference*

---

## Description

Position data for the 40 standard Munsell hues (and neutral). Data include angular positions (compass-style, origin at  $[x = 0, y = 1]$ , CW rotation) and Cartesian coordinates on the unit circle.

## Usage

```
data(munsellHuePosition)
```

## Format

An object of class `data.frame` with 41 rows and 4 columns.

## References

Munsell book of color. 1976. Macbeth, a Division of Kollmorgen Corp., Baltimore, MD.

---

mutate_profile	<i>Transform a SPC (by profile) with a set of expressions</i>
----------------	---

---

### Description

mutate\_profile() is a function used for transforming SoilProfileCollections. Each expression is applied to site or horizon level attributes of individual profiles. This distinguishes this function from transform, which is applied to all values in a collection, regardless of which profile they came from.

### Usage

```
mutate_profile(object, ..., horizon_level = NULL)
```

### Arguments

object	A SoilProfileCollection
...	A set of comma-delimited R expressions that resolve to a transformation to be applied to a single profile e.g mutate_profile(hzdept = max(hzdept) - hzdept)
horizon_level	logical. If TRUE results of expressions are added to the SoilProfileCollection's horizon slot, if FALSE the results are added to the site slot. If NULL (default) the results are stored in the site or horizon slot based on the number of rows in each slot compared to the length of the result calculated from the <i>first</i> and <i>last</i> profile in the collection.

### Details

If the length an expression's result matches the number of horizons, the result is stored as a horizon-level variable. If the result has length 1, it is stored as a site-level variable. In the ambiguous case where the first and last profile have only *one* horizon, the results are stored in the horizon slot by default. To force results into site slot use horizon\_level = FALSE.

### Value

A SoilProfileCollection.

### Author(s)

Andrew G. Brown.

---

 names,SoilProfileCollection-method

*Get names of columns in site and horizons table*

---

### Description

Get names of columns in site and horizons table of a SoilProfileCollection.

### Usage

names(x)
```

### Arguments

x                    a SoilProfileCollection

---

 NCSP

*Numerical Classification of Soil Profiles*

---

### Description

Replacement for profile\_compare().

Performs a numerical comparison of soil profiles using named properties, based on a weighted, summed, depth-segment-aligned dissimilarity calculation.

Variability in soil depth can interfere significantly with the calculation of between-profile dissimilarity—what is the numerical “distance” (or dissimilarity) between a slice of soil from profile A and the corresponding, but missing, slice from a shallower profile B? Gower’s distance metric would yield a NULL distance, despite the fact that intuition suggests otherwise: shallower soils should be more dissimilar from deeper soils. For example, when a 25 cm deep profile is compared with a 50 cm deep profile, numerical distances are only accumulated for the first 25 cm of soil (distances from 26 - 50 cm are NULL). When summed, the total distance between these profiles will generally be less than the distance between two profiles of equal depth. Our algorithm has an option (setting replace\_na=TRUE) to replace NULL distances with the maximum distance between any pair of profiles for the current depth slice. In this way, the numerical distance between a slice of soil and a corresponding slice of non-soil reflects the fact that these two materials should be treated very differently (i.e. maximum dissimilarity).

This alternative calculation of dissimilarities between soil and non-soil slices solves the problem of comparing shallow profiles with deeper profiles. However, it can result in a new problem: distances calculated between two shallow profiles will be erroneously inflated beyond the extent of either profile’s depth. Our algorithm has an additional option (setting add\_soil\_flag=TRUE) that will preserve NULL distances between slices when both slices represent non-soil material. With this option enabled, shallow profiles will only accumulate mutual dissimilarity to the depth of the deeper profile.

Slices are classified as 'soil' down to the maximum depth to which at least one of variables used in the dissimilarity calculation is not NA. This will cause problems when profiles within a collection contain all NAs within the columns used to determine dissimilarity. An approach for identifying and removing these kind of profiles is presented in the examples section below.

A notice is issued if there are any NA values within the matrix used for distance calculations, as these values are optionally replaced by the max dissimilarity.

Our approach builds on the work of (Moore, 1972) and the previously mentioned depth-slicing algorithm.

### Usage

```
NCSP(
  x,
  vars,
  fm = NULL,
  weights = rep(1, times = length(vars)),
  maxDepth = max(x),
  k = 0,
  isColor = FALSE,
  rescaleResult = FALSE,
  progress = TRUE,
  verbose = TRUE,
  returnDepthDistances = FALSE
)
```

### Arguments

<code>x</code>	SoilProfileCollection object, should be pre-filtered to remove profiles with horizon depth logic, see <a href="#">HzDepthLogicSubset</a>
<code>vars</code>	character vector, names of horizon attributes to use in the classification
<code>fm</code>	formula, formula as specified to <a href="#">dice()</a> , not yet implemented
<code>weights</code>	numeric vector, same length as <code>vars</code> : variable importance weights, need not sum to 1
<code>maxDepth</code>	numeric, maximum depth of analysis
<code>k</code>	numeric, weighting coefficient, see examples
<code>isColor,</code>	logical: variables represent color, should be CIELAB coordinates (D65 illuminant), weights are ignored. Variables should be named L, A, B in specified in that order.
<code>rescaleResult</code>	logical, distance matrix is rescaled based on <code>max(D)</code>
<code>progress</code>	logical, report progress
<code>verbose</code>	logical, extra output messages
<code>returnDepthDistances</code>	logical, return a list of distances by depth slice

### Note

NCSP() will overwrite the `removed.profiles` metadata from `x`.

**Format**

A SoilProfileCollection

---

```
panel.depth_function
```

*Lattice Panel Function for Soil Profiles*

---

**Description**

Panel function for plotting grouped soil property data, along with upper and lower estimates of uncertainty.

This function can be used to replace panel.superpose when plotting depth function data. When requested, contributing fraction data are printed using colors the same color as corresponding depth function lines unless a single color value is given via cf.col.

This function is not able to apply transformations (typically log = 10) applied in the scales argument to xyplot to upper/lower bounds. These will have to be manually applied. See examples.

**Usage**

```
panel.depth_function(
  x,
  y,
  id,
  upper = NA,
  lower = NA,
  subscripts = NULL,
  groups = NULL,
  sync.colors = FALSE,
  cf = NA,
  cf.col = NA,
  cf.interval = 20,
  ...
)
```

```
prepanel.depth_function(
  x,
  y,
  upper = NA,
  lower = NA,
  subscripts,
  groups = NULL,
  ...
)
```

### Arguments

x	x values (generated by calling lattice function)
y	y values (generated by calling lattice function)
id	vector of id labels, same length as x and y—only required when plotting segments (see Details section)
upper	vector of upper confidence envelope values
lower	vector of lower confidence envelope values
subscripts	paneling indices (generated by calling lattice function)
groups	grouping data (generated by calling lattice function)
sync.colors	optionally sync the fill color within the region bounded by (lower–upper) with the line colors
cf	optionally annotate contributing fraction data at regular depth intervals see <a href="#">slab</a>
cf.col	optional color for contributing fraction values, typically used to override the line color
cf.interval	number of depth units to space printed contributing fraction values
...	further arguments to lower-level lattice plotting functions, see below

}

```

## Description

Split Munsell color notation into "hue", "value", and "chroma", with optional conversion to sRGB hex notation, sRGB coordinates, and CIELAB coordinates. Conversion is performed by [munsell2rgb](#).

## Usage

```
parseMunsell(munsellColor, convertColors = TRUE, delim = NA, ...)
```

## Arguments

munsellColor	character vector of Munsell colors (e.g. <code>c('10YR 3/4', '5YR 4/6')</code> )
convertColors	logical, convert colors to sRGB hex notation, sRGB coordinates, CIELAB coordinates
delim	optional, specify the type of delimiter used between value and chroma parts of the Munsell code. By default ":", ":", "'", and "/" are supported.
...	additional arguments to <a href="#">munsell2rgb</a>

## Value

a data.frame object

## Author(s)

P. Roudier and D.E. Beaudette

## Examples

```
# just sRGB
parseMunsell("10YR 3/5", return_triplets = TRUE)

# sRGB + CIELAB (D65 illuminant)
parseMunsell("10YR 3/5", return_triplets = TRUE, returnLAB = TRUE)

# CIELAB only
parseMunsell("10YR 3/5", return_triplets = FALSE, returnLAB = TRUE)

# neutral hue
# note chroma encoded as '0'
parseMunsell('N 3/', convertColors = FALSE)
```

---

pbindlist

*Combine a list of SoilProfileCollection objects*

---

### Description

See `combine(...)` for a connotative short-hand method that does not require that `SoilProfileCollection` be in a list. Profiles will be sorted based on character sorting of profile ID.

### Usage

```
pbindlist(l, new.idname = NULL, verbose = TRUE)
```

### Arguments

<code>l</code>	a list of <code>SoilProfileCollection</code> objects
<code>new.idname</code>	Optional: a character referring to a new column name to put unique profile IDs in; default: <code>NULL</code> to attempt with existing <code>idname</code> in first element
<code>verbose</code>	Produce warnings and messages regarding results? default: <code>TRUE</code>

### Details

Input data must share a common depth unit, and if spatial data are present, a common CRS and coordinate names. In the case of non-conformal `@idname` and/or `@depthcols`, the first `SoilProfileCollection` is used as a template. If one or more subsequent list elements has non-unique values in a site level attribute of that name, the ID name from the second list element is attempted, and so on. Non-conforming spatial data are dropped from the final result (returns default empty `SpatialPoints`).

### Value

a `SoilProfileCollection` object

### Author(s)

D.E. Beaudette and A.G. Brown

### Examples

```
# example data
data(sp2, package = 'aqp')
depths(sp2) <- id ~ top + bottom
site(sp2) <- ~ surface

# copy pieces
x <- sp2[1:5, ]
y <- sp2[6:10, ]

# reset IDs and combine
```

```

profile_id(y) <- sprintf("%s-copy", profile_id(y))

# this should work
z <- pbindlist(list(x, y))

# check
plot(z)

```

---

pc

*Deprecated: Numerical Soil Profile Comparison*

---

## Description

See NCSP() for the modern interface to numerical soil profile comparison/classification.

## Usage

```

pc(
  s,
  vars,
  max_d,
  k,
  filter = NULL,
  sample_interval = NA,
  replace_na = TRUE,
  add_soil_flag = TRUE,
  return_depth_distances = FALSE,
  strict_hz_eval = FALSE,
  progress = "none",
  plot.depth.matrix = FALSE,
  rescale.result = FALSE,
  verbose = FALSE
)

pc.SPC(s, vars, rescale.result = FALSE, ...)

## S4 method for signature 'SoilProfileCollection'
profile_compare(s, vars, rescale.result = FALSE, ...)

## S4 method for signature 'data.frame'
profile_compare(
  s,
  vars,
  max_d,
  k,
  filter = NULL,
  sample_interval = NA,

```

```

    replace_na = TRUE,
    add_soil_flag = TRUE,
    return_depth_distances = FALSE,
    strict_hz_eval = FALSE,
    progress = "none",
    plot.depth.matrix = FALSE,
    rescale.result = FALSE,
    verbose = FALSE
  )

```

### Arguments

<code>s</code>	A <code>SoilProfileCollection</code>
<code>vars</code>	Variable names
<code>max_d</code>	depth-slices up to this depth are considered in the comparison
<code>k</code>	a depth-weighting coefficient, use '0' for no depth-weighting (see examples below)
<code>filter</code>	an index used to determine which horizons (rows) are included in the analysis
<code>sample_interval</code>	use every n-th depth slice instead of every depth slice, useful for working with > 1000 profiles at a time
<code>replace_na</code>	if TRUE, missing data are replaced by maximum dissimilarity (TRUE)
<code>add_soil_flag</code>	The algorithm will generate a 'soil'/'non-soil' matrix for use when comparing soil profiles with large differences in depth (TRUE). See details section below.
<code>return_depth_distances</code>	return intermediate, depth-wise dissimilarity results (FALSE)
<code>strict_hz_eval</code>	should horizons be strictly checked for internal self-consistency? (FALSE)
<code>progress</code>	'none' (default)
<code>plot.depth.matrix</code>	should a plot of the 'soil'/'non-soil' matrix be returned (FALSE)
<code>rescale.result</code>	Rescale result? Default: FALSE
<code>verbose</code>	extra debug output (FALSE)
<code>...</code>	Additional arguments passed to <code>profile_compare()</code>

### Details

Performs a numerical comparison of soil profiles using named properties, based on a weighted, summed, depth-segment-aligned dissimilarity calculation. If `s` is a `SoilProfileCollection`, site-level variables (2 or more) can also be used. The site-level and horizon-level dissimilarity matrices are then re-scaled and averaged.

Variability in soil depth can interfere significantly with the calculation of between-profile dissimilarity—what is the numerical “distance” (or dissimilarity) between a slice of soil from profile A and the corresponding, but missing, slice from a shallower profile B? Gower’s distance metric would yield a NULL distance, despite the fact that intuition suggests otherwise: shallower soils should be more dissimilar from deeper soils. For example, when a 25 cm deep profile is compared with a 50 cm

deep profile, numerical distances are only accumulated for the first 25 cm of soil (distances from 26 - 50 cm are NULL). When summed, the total distance between these profiles will generally be less than the distance between two profiles of equal depth. Our algorithm has an option (setting `replace_na=TRUE`) to replace NULL distances with the maximum distance between any pair of profiles for the current depth slice. In this way, the numerical distance between a slice of soil and a corresponding slice of non-soil reflects the fact that these two materials should be treated very differently (i.e. maximum dissimilarity).

This alternative calculation of dissimilarities between soil and non-soil slices solves the problem of comparing shallow profiles with deeper profiles. However, it can result in a new problem: distances calculated between two shallow profiles will be erroneously inflated beyond the extent of either profile's depth. Our algorithm has an additional option (setting `add_soil_flag=TRUE`) that will preserve NULL distances between slices when both slices represent non-soil material. With this option enabled, shallow profiles will only accumulate mutual dissimilarity to the depth of the deeper profile.

Note that when the `add_soil_flag` option is enabled (default), slices are classified as 'soil' down to the maximum depth to which at least one of variables used in the dissimilarity calculation is not NA. This will cause problems when profiles within a collection contain all NAs within the columns used to determine dissimilarity. An approach for identifying and removing these kind of profiles is presented in the examples section below.

A notice is issued if there are any NA values within the matrix used for distance calculations, as these values are optionally replaced by the max dissimilarity.

Our approach builds on the work of (Moore, 1972) and the previously mentioned depth-slicing algorithm.

### Value

A dissimilarity matrix object of class 'dissimilarity, dist', optionally scaled by `max(D)`.

 perturb

*Perturb soil horizon depths using boundary distinctness*

---

### Description

"Perturbs" the **boundary between horizons** or the **thickness of horizons** using a standard deviation specified as a horizon-level attribute. This is selected using either `boundary.attr` or `thickness.attr` to specify the column name.

The boundary standard deviation corresponds roughly to the concept of "horizon boundary distinctness." In contrast, the *horizon thickness* standard deviation corresponds roughly to the "variation in horizon thickness" so it may be determined from several similar profiles that have a particular layer "in common."

### Usage

```
perturb(
  p,
  n = 100,
  id = NULL,
  thickness.attr = NULL,
  boundary.attr = NULL,
  min.thickness = 1,
  max.depth = NULL,
  new.idname = "pID"
)
```

### Arguments

<code>p</code>	A SoilProfileCollection
<code>n</code>	Number of new profiles to generate (default: 100) per profile in <code>p</code>
<code>id</code>	a vector of profile IDs with length equal to <code>(n)</code> . Overrides use of <code>seq_len(n)</code> as default profile ID values.
<code>thickness.attr</code>	Horizon variance attribute containing numeric "standard deviations" reflecting horizon thickness
<code>boundary.attr</code>	Horizon variance attribute containing numeric "standard deviations" reflecting boundary transition distinctness
<code>min.thickness</code>	Minimum thickness of permuted horizons (default: 1)
<code>max.depth</code>	Depth below which horizon depths are not perturbed (default: NULL)
<code>new.idname</code>	New column name to contain unique profile ID (default: pID)

### Details

Imagine a Normal curve with mean centered on the vertical (depth axis) at a representative value (RV) horizon bottom depth or thickness. By the Empirical Rule for Normal distribution, two "standard deviations" above or below that "central" mean value represent 95% of the "typical volume" of that horizon or boundary.

`perturb()` can leverage semi-quantitative (ordered factor) levels of boundary distinctness/topography for the upper and lower boundary of individual horizons. A handy function for this is [hzDistinctnessCodeToOffset\(\)](#). The `boundary.attr` is arguably easier to parameterize from a single profile description or "Form 232" where *horizon boundary distinctness* classes (based on vertical distance of transition) are conventionally recorded for each layer.

Alternately, `perturb()` can be parameterized using standard deviation in thickness of layers derived from a group. Say, the variance parameters are defined from a set of pedons correlated to a particular series or component, and the template "seed" profile is, for example, the Official Series Description or the Representative Component Pedon.

### Value

a `SoilProfileCollection` with `n` realizations of each profile in `p`

### BOUNDARIES

# example with sp1 (using boundary distinctness)
data("sp1")

```

```

depths(sp1) <- id ~ top + bottom

# specify "standard deviation" for boundary thickness
# consider a normal curve centered at boundary RV depth
# lookup table: ~maximum thickness of boundary distinctness classes, divided by 3
bound.lut <- c('V'=0.5, 'A'=2, 'C'=5, 'G'=15, 'D'=45) / 3

## V      A      C      G      D
## 0.1666667 0.6666667 1.6666667 5.0000000 15.0000000

sp1$bound_sd <- bound.lut[sp1$bound_distinct]

# hold any NA boundary distinctness constant
sp1$bound_sd[is.na(sp1$bound_sd)] <- 0

quantile(sp1$bound_sd, na.rm = TRUE)
p <- sp1[3]

# assume boundary sd is 1/12 midpoint of horizon depth
# (i.e. general relationship: SD increases (less well known) with depth)
sp1 <- transform(sp1, midpt = (bottom - top) / 2 + top, bound_sd = midpt / 12)
quantile(sp1$bound_sd)

perturb(p, boundary.attr = "bound_sd", n = 10)

### Custom IDs

ids <- sprintf("%s-%03d", profile_id(p), 1:10)
perturb(p, boundary.attr = "bound_sd", id = ids)

```

---

ph\_to\_rxnclass

*Convert pH to/from Reaction Classes*

---

### Description

Convert pH to/from Reaction Classes

### Usage

```
ph_to_rxnclass(x, halfclass = FALSE, as.is = FALSE, droplevels = TRUE)
```

```
rxnclass_to_ph(x, halfclass = FALSE, digits = 2, simplify = TRUE)
```

```
ReactionClassLevels(halfclass = FALSE, as.is = FALSE)
```

**Arguments**

x	input pH values (numeric; <code>ph_to_rxnclass()</code> ) or reaction classes (character; <code>rxnclass_to_ph()</code> )
halfclass	Split the standard classes in half for higher resolution? Default: FALSE
as.is	logical. Should character vectors be converted to factors? Default: FALSE
droplevels	logical. Drop unused levels in factors? Default: FALSE
digits	Number of digits after decimal place; Default: 2. Used only for <code>rxnclass_to_ph()</code>
simplify	Simplify list result to numeric vector when length of result is 1? Default: TRUE

**Value**

`ph_to_rxnclass()`: a vector of reaction classes corresponding to numeric input in `x`; if `as.is=FALSE` an ordered factor using `ReactionClassLevels()`

`rxnclass_to_ph()`: a list of data.frame objects containing high/low values of reaction class 1:1 with input; if `simplify=TRUE` and input is a data.frame.

`ReactionClassLevels()`: ordered factor containing descriptive terms for reaction classes

**Examples**

```
ph_to_rxnclass(6.2)
rxnclass_to_ph("slightly acid")

rxnclass_to_ph(list(c("Slightly Acid", NA, "Moderately Acid"),
                   c("Slightly Acid", NA, "Strongly Acid")), simplify = FALSE)
ReactionClassLevels()
```

---

plotColorMixture

*Visualize Spectral Mixing of Munsell Colors*

---

**Description**

Lattice visualization demonstrating subtractive mixtures of colors in Munsell notation and associated spectra.

**Usage**

```
plotColorMixture(
  x,
  w = rep(1, times = length(x))/length(x),
  mixingMethod = c("exact", "reference"),
  n = 1,
  swatch.cex = 1.5,
  label.cex = 0.85,
  showMixedSpec = FALSE,
  overlapFix = TRUE
)
```

**Arguments**

x	vector of colors in Munsell notation, should not contain duplicates
w	vector of weights, can sum to any number
mixingMethod	approach used to simulate a mixture: <ul style="list-style-type: none"><li>• exact: simulate a subtractive mixture of pigments, color conversion via CIE1931 color-matching functions (see <a href="#">mixMunsell()</a>)</li><li>• reference : simulate a subtractive mixture of pigments, selecting n closest reference spectra, requires gower package</li></ul>
n	number of closest mixture candidates when mixingMethod = 'reference' (see <a href="#">mixMunsell()</a> ), results can be hard to interpret when $n > 2$
swatch.cex	scaling factor for color swatch rectangle width and height, relative to label.cex, typically between 1 and 3
label.cex	scaling factor for swatch labels
showMixedSpec	show weighted geometric mean (mixed) spectra as dotted line (only when mixingMethod = 'reference')
overlapFix	attempt to "fix" overlapping chip labels via <a href="#">fixOverlap()</a> , using method = 'E'

**Details**

If present, names attribute of x is used for the figure legend. See the [expanded tutorial](#) for examples.

**Value**

a lattice graphics object

**Author(s)**

D.E. Beaudette

**See Also**

[mixMunsell\(\)](#)

---

plotColorQuantiles      *Visualize Color Quantiles*

---

**Description**

This function creates a visualization of the output from colorQuantiles using lattice graphics.

**Usage**

```
plotColorQuantiles(res, pt.cex = 7, lab.cex = 0.66)
```

**Arguments**

res	list returned by colorQuantiles
pt.cex	scaling factor for color chips
lab.cex	chip label scaling factor

**Details**

Marginal percentiles and L1 median CIELAB values from colorQuantiles() are combined into a single plot, arranged in panels according to L, A, and B coordinates. Munsell "chips" (colors and labels) are based on the closest Munsell color found via col2Munsell().

**Value**

a lattice graphics object

**Author(s)**

D.E. Beaudette

---

plotMultipleSPC

*Plot Multiple SoilProfileCollection Objects*

---

**Description**

Plot Multiple SoilProfileCollection Objects

**Usage**

```
plotMultipleSPC(
  spc.list,
  group.labels,
  args = rep(list(NA), times = length(spc.list)),
  merged.legend = NULL,
  merged.colors = c("#5E4FA2", "#3288BD", "#66C2A5", "#ABDDA4", "#E6F598", "#FEE08B",
    "#FDAE61", "#F46D43", "#D53E4F", "#9E0142"),
  merged.legend.title = merged.legend,
  arrow.offset = 2,
  bracket.base.depth = 95,
  label.offset = 2,
  label.cex = 0.75,
  ...
)
```

**Arguments**

spc.list	a list of SoilProfileCollection objects
group.labels	a vector of group labels, one for each SoilProfileCollection object
args	a list of arguments passed to plotSPC, one for each SoilProfileCollection object
merged.legend	name of a horizon level attribute from which to create thematic sketches and merged legend
merged.colors	vector of colors used to create thematic sketches from a shared horizon level attribute
merged.legend.title	legend title
arrow.offset	vertical offset in depth from base of start / end profiles and group bracket arrows
bracket.base.depth	baseline depth used for group brackets
label.offset	vertical offset of group labels from baseline
label.cex	label size
...	additional arguments to the first call to plotSPC

**Details**

Combine multiple SoilProfileCollection objects into a single profile sketch, with annotated groups.

See examples below for usage.

**Note**

For thematic sketches, use the merged.legend argument instead of color argument to plotSPC

**Author(s)**

D.E. Beaudette and Ben Marshall

**Examples**

```
##
## Simple Example
##

# using default arguments to plotSPC()

# load sample data
data(sp3)
```

```

data(sp4)

# promote to SoilProfileCollection
depths(sp3) <- id ~ top + bottom
depths(sp4) <- id ~ top + bottom

# combine into a list
spc.list <- list(sp3, sp4)

# argument list
arg.list <- list(
  list(name='name', id.style='top'),
  list(name='name', id.style='side')
)

# plot multiple SPC objects,
# with list of named arguments for each call to plotSPC
par(mar=c(1,1,3,3))
plotMultipleSPC(
  spc.list,
  group.labels = c('Collection 1', 'Collection 2'),
  args = arg.list,
  bracket.base.depth = 120, label.cex = 1
)

# specify a different max.depth
plotMultipleSPC(
  spc.list,
  group.labels = c('Collection 1', 'Collection 2'),
  args = arg.list,
  bracket.base.depth = 120, label.cex = 1,
  max.depth = 250
)

##
## Merged Legend Example
##

# merged legend based on hz attribute 'clay'

# reset sample data
data(sp3)
data(sp4)

# promote to SoilProfileCollection
depths(sp3) <- id ~ top + bottom
depths(sp4) <- id ~ top + bottom

# combine into a list
spc.list <- list(sp3, sp4)

```

```

# argument list
arg.list <- list(
  list(name='name', id.style='top'),
  list(name='name', id.style='side')
)

par(mar=c(1,1,3,3))
plotMultipleSPC(
  spc.list,
  group.labels = c('Collection 1', 'Collection 2'),
  args = arg.list,
  label.cex = 1,
  merged.legend = 'clay', merged.legend.title = 'Clay (%)'
)

##
## Complex Merged Legend Example
##

# create a merged legend from "clay" in sp4 and jacobs2000
# use "soil_color" from sp3

# reset sample data
data(sp3)
data(sp4)
data(jacobs2000)

# promote to SoilProfileCollection
depths(sp3) <- id ~ top + bottom
depths(sp4) <- id ~ top + bottom

# remove 'clay' column from sp3
sp3$clay <- NULL

# combine into a list
spc.list <- list(sp3, sp4, jacobs2000)

# try some variations on the default arguments
# `clay` is missing in the first SPC, safe to specify another column for colors
arg.list <- list(
  list(color = 'soil_color', id.style='top', name = NA, width = 0.3, hz.depths = TRUE),
  list(name='name', id.style='side', name.style = 'center-center'),
  list(name='name', id.style='side', name.style = 'left-center', hz.depths = TRUE)
)

par(mar=c(1,1,3,3))
plotMultipleSPC(
  spc.list,
  group.labels = c('sp3', 'sp4', 'jacobs2000'),
  label.offset = 3,

plotSPC

*Create Soil Profile Sketches*

---

## Description

Generate a diagram of soil profile sketches from a `SoilProfileCollection` object. The [Introduction to SoilProfileCollection Objects Vignette](#) contains many examples and discussion of the large number of arguments to this function. The [Soil Profile Sketches](#) tutorial has longer-form discussion and examples pertaining to suites of related arguments.

Options can be used to conveniently specify sets of arguments that will be used in several calls to `plotSPC()` within a single R session. For example, arguments can be specified in a named list (`.a`) and set using: `options(.aqp.plotSPC.args = .a)`. Reset these options via `options(.aqp.plotSPC.args = NULL)`. Arguments explicitly passed to `plotSPC()` will override arguments set via `options()`.

## Usage

```
plotSPC(
  x,
  color = "soil_color",
  width = ifelse(length(x) < 2, 0.15, 0.25),
  name = hzdesgname(x),
  name.style = "right-center",
  label = idname(x),
  raggedBottom = NULL,
  hz.depths = FALSE,
  hz.depths.offset = ifelse(fixLabelCollisions, 0.03, 0),
  hz.depths.lines = fixLabelCollisions,
  depth.axis = list(style = "traditional", cex = cex.names * 1.15),
  alt.label = NULL,
  alt.label.col = "black",
  cex.names = 0.5,
  cex.id = cex.names + (0.2 * cex.names),
  font.id = 2,
  srt.id = 0,
  print.id = TRUE,
  id.style = "auto",
  plot.order = 1:length(x),
  relative.pos = 1:length(x),
  add = FALSE,
  scaling.factor = 1,
  y.offset = rep(0, times = length(x)),
  x.idx.offset = 0,
  n = length(x),
```

```

max.depth = ifelse(is.infinite(max(x)), 200, max(x)),
n.depth.ticks = 10,
shrink = FALSE,
shrink.cutoff = 3,
shrink.thin = NULL,
abbr = FALSE,
abbr.cutoff = 5,
divide.hz = TRUE,
hz.distinctness.offset = NULL,
hz.topography.offset = NULL,
hz.boundary.lty = NULL,
density = NULL,
show.legend = TRUE,
col.label = color,
col.palette = c("#5E4FA2", "#3288BD", "#66C2A5", "#ABDDA4", "#E6F598", "#FEE08B",
  "#FDAE61", "#F46D43", "#D53E4F", "#9E0142"),
col.palette.bias = 1,
col.legend.cex = 1,
n.legend = 8,
lwd = 1,
lty = 1,
default.color = grey(0.95),
fixLabelCollisions = hz.depths,
fixOverlapArgs = list(method = "E", q = 1),
cex.depth.axis = cex.names,
axis.line.offset = -2,
plot.depth.axis = TRUE,
...
)

## S4 method for signature 'SoilProfileCollection,ANY'
plot(x, y, ...)

```

### Arguments

<code>x</code>	a <code>SoilProfileCollection</code> object
<code>color</code>	quoted column name containing R-compatible color descriptions, or numeric / categorical data to be displayed thematically; see details
<code>width</code>	scaling of profile widths (typically 0.1 - 0.4)
<code>name</code>	quoted column name of the (horizon-level) attribute containing horizon designations or labels, if missing <code>hzdesignname(x)</code> is used. Suppress horizon name printing by setting <code>name = NA</code> or <code>name = ''</code> .
<code>name.style</code>	one of several possible horizon designations labeling styles: <code>c('right-center', 'left-center', 'left-top', 'center-center', 'center-top')</code>
<code>label</code>	quoted column name of the (site-level) attribute used to identify profile sketches
<code>raggedBottom</code>	either quoted column name of the (site-level) attribute (logical) used to mark profiles with a truncated lower boundary, or <code>FALSE</code> suppress ragged bottom depths when <code>max.depth &lt; max(x)</code>

hz.depths	logical, annotate horizon top depths to the right of each sketch (FALSE)
hz.depths.offset	numeric, user coordinates for left-right adjustment for horizon depth annotation; reasonable values are usually within 0.01-0.05 (default: 0)
hz.depths.lines	logical, draw segments between horizon depth labels and actual horizon depth; this is useful when including horizon boundary distinctness and/or fixLabelCollisions = TRUE
depth.axis	logical or list. Use a logical to suppress (FALSE) or add depth axis using defaults (TRUE). Use a list to specify one or more of: <ul style="list-style-type: none"> <li>• style: character, one of 'traditional', 'compact', or 'tape'</li> <li>• line: numeric, negative values move axis to the left (does not apply to style = 'tape')</li> <li>• cex: numeric, scaling applied to entire depth axis</li> <li>• interval: numeric, axis interval See examples.</li> </ul>
alt.label	quoted column name of the (site-level) attribute used for secondary annotation
alt.label.col	color used for secondary annotation text
cex.names	baseline character scaling applied to all text labels
cex.id	character scaling applied to label
font.id	font style applied to label, default is 2 (bold)
srt.id	rotation applied to label, only when id.style = 'top'
print.id	logical, print label above/beside each profile? (TRUE)
id.style	label printing style: 'auto' (default) = simple heuristic used to select from: 'top' = centered above each profile, 'side' = 'along the top-left edge of profiles'
plot.order	integer vector describing the order in which individual soil profiles should be plotted
relative.pos	vector of relative positions along the x-axis, within {1, n}, ignores plot.order see details
add	logical, add to an existing figure
scaling.factor	vertical scaling of profile depths, useful for adding profiles to an existing figure
y.offset	numeric vector of vertical offset for top of profiles in depth units of x, can either be a single numeric value or vector of length = length(x). A vector of y-offsets will be automatically re-ordered according to plot.order.
x.idx.offset	integer specifying horizontal offset from 0 (left-hand edge)
n	integer describing amount of space along x-axis to allocate, defaults to length(x)
max.depth	numeric. The lower depth for all sketches, deeper profiles are truncated at this depth. Use larger values to arbitrarily extend the vertical dimension, convenient for leaving extra space for annotation.
n.depth.ticks	suggested number of ticks in depth scale
shrink	logical, reduce character scaling for 'long' horizon by 80%
shrink.cutoff	character length defining 'long' horizon names

<code>shrink.thin</code>	integer, horizon thickness threshold for shrinking horizon names by 80%, only activated when <code>shrink = TRUE</code> (NULL = no shrinkage)
<code>abbr</code>	logical, abbreviate label
<code>abbr.cutoff</code>	suggested minimum length for abbreviated label
<code>divide.hz</code>	logical, divide horizons with line segment? (TRUE), see details
<code>hz.distinctness.offset</code>	NULL, or quoted column name (horizon-level attribute) containing vertical offsets used to depict horizon boundary distinctness (same units as profiles), see details and <a href="#">hzDistinctnessCodeToOffset()</a> ; consider setting <code>hz.depths.lines = TRUE</code> when used in conjunction with <code>hz.depths = TRUE</code>
<code>hz.topography.offset</code>	NULL, or quoted column name (horizon-level attribute) containing offsets used to depict horizon boundary topography (same units as profiles), see details and <a href="#">hzTopographyCodeToOffset()</a>
<code>hz.boundary.lty</code>	quoted column name (horizon-level attribute) containing line style (integers) used to encode horizon topography
<code>density</code>	fill density used for horizon color shading, either a single integer or a quoted column name (horizon-level attribute) containing integer values (default is NULL, no shading)
<code>show.legend</code>	logical, show legend? (default is TRUE)
<code>col.label</code>	thematic legend title
<code>col.palette</code>	color palette used for thematic sketches (default is <code>rev(brewer.pal(10, 'Spectral'))</code> )
<code>col.palette.bias</code>	color ramp bias (skew), see <a href="#">colorRamp()</a>
<code>col.legend.cex</code>	scaling of thematic legend
<code>n.legend</code>	approximate number of classes used in numeric legend, max number of items per row in categorical legend
<code>lwd</code>	line width multiplier used for sketches
<code>lty</code>	line style used for sketches
<code>default.color</code>	default horizon fill color used when color attribute is NA
<code>fixLabelCollisions</code>	use <a href="#">fixOverlap()</a> to attempt fixing hz depth labeling collisions, will slow plotting of large collections; enabling also sets <code>hz.depths.lines = TRUE</code> . Additional arguments to <a href="#">fixOverlap()</a> can be passed via <code>fixOverlapArgs</code> . Overlap collisions cannot be fixed within profiles containing degenerate or missing horizon depths (e.g. <code>top == bottom</code> ).
<code>fixOverlapArgs</code>	a named list of arguments to <a href="#">fixOverlap()</a> . Overlap adjustments are attempted using electrostatic simulation with arguments: <code>list(method = 'E', q = 1)</code> . Alternatively, select adjustment by simulated annealing via <code>list(method = 'S')</code> . See <a href="#">electroStatics_1D()</a> and <a href="#">SANN_1D()</a> for details.
<code>cex.depth.axis</code>	(deprecated, use <code>depth.axis</code> instead) character scaling applied to depth scale

```

axis.line.offset
    (deprecated, use depth.axis instead) horizontal offset applied to depth axis
    (default is -2, larger numbers move the axis to the right)
plot.depth.axis
    (deprecated, use depth.axis instead) logical, plot depth axis?
...
    other arguments passed into lower level plotting functions
y
    (not used)

```

## Details

Depth limits (`max.depth`) and number of depth ticks (`n.depth.ticks`) are *suggestions* to the `pretty()` function. You may have to tinker with both parameters to get what you want.

The `'side'` `id.style` is useful when plotting a large collection of profiles, and/or, when profile IDs are long.

If the column containing horizon designations is not specified (the `name` argument), a column (presumed to contain horizon designation labels) is guessed based on regular expression matching of the pattern `'name'`—this usually works, but it is best to manually specify the name of the column containing horizon designations.

The `color` argument can either name a column containing R-compatible colors, possibly created via `munsell2rgb()`, or column containing either numeric or categorical (either factor or character) values. In the second case, values are converted into colors and displayed along with a simple legend above the plot. Note that this functionality makes several assumptions about plot geometry and is most useful in an interactive setting.

Adjustments to the legend can be specified via `col.label` (legend title), `col.palette` (palette of colors, automatically expanded), `col.legend.cex` (legend scaling), and `n.legend` (approximate number of classes for numeric variables, or, maximum number of legend items per row for categorical variables). Currently, plotSPC will only generate two rows of legend items. Consider reducing the number of classes if two rows isn't enough room.

Profile sketches can be added according to relative positions along the x-axis (vs. integer sequence) via `relative.pos` argument. This should be a vector of positions within  $\{1, n\}$  that are used for horizontal placement. Default values are `1:length(x)`. Care must be taken when both `plot.order` and `relative.pos` are used simultaneously: `relative.pos` specifies horizontal placement after sorting. `addDiagnosticBracket()` and `addVolumeFraction()` use the `relative.pos` values for subsequent annotation.

Relative positions that are too close will result in overplotting of sketches. Adjustments to relative positions such that overlap is minimized can be performed with `fixOverlap(pos)`, where `pos` is the original vector of relative positions.

The `x.idx.offset` argument can be used to shift a collection of pedons from left to right in the figure. This can be useful when plotting several different `SoilProfileCollection` objects within the same figure. Space must be pre-allocated in the first plotting call, with an offset specified in the second call. See examples below.

Horizon depths (e.g. cm) are converted to figure y-coordinates via:  $y = (\text{depth} * \text{scaling.factor}) + y.\text{offset}$ .

## Note

A new plot of soil profiles is generated, or optionally added to an existing plot.

box()

```

**Description**

Plot pair-wise distances between individuals as line segments.

**Usage**

```
plot_distance_graph(D, idx = 1:dim(as.matrix((D)))[1])
```

**Arguments**

D	distance matrix, should be of class 'dist' or compatible class
idx	an integer sequence defining which individuals should be compared

**Details**

By default all individuals are plotting on the same axis. When there are more than about 10 individuals, the plot can become quite messy. See examples below for ideas.

**Value**

No value is returned.

**Author(s)**

Dylan E Beaudette

**References**

<http://casoilresource.lawr.ucdavis.edu/>

**Examples**

```
data(sp2)
depths(sp2) <- id ~ top + bottom
d <- NCSP(
  sp2,
  vars = c('prop', 'field_ph', 'hue', 'value'),
  maxDepth = 100,
  k = 0.01
)

par(mfcol=c(3,1), mar=c(2.5,4.5,1,1))
plot_distance_graph(d, idx=1:6)
plot_distance_graph(d, idx=7:12)
plot_distance_graph(d, idx=12:18)
```

---

```
previewColors      Preview Colors
```

---

### Description

Preview colors arranged according to CIE2000 distances or manual specification.

### Usage

```
previewColors(  
  cols,  
  method = c("grid", "MDS", "manual"),  
  labels = NULL,  
  labels.cex = 1,  
  col.order = NULL,  
  nrow = ceiling(sqrt(length(cols))),  
  ncol = nrow,  
  border.col = "black",  
  pt.cex = 2,  
  pt.pch = 15  
)
```

### Arguments

<code>cols</code>	vector of R colors
<code>method</code>	either "grid", "MDS", or "manual", see details
<code>labels</code>	optional vector of labels, disabled when <code>length(cols) &gt; 5000</code>
<code>labels.cex</code>	scaling factor for labels
<code>col.order</code>	integer vector used to order colors
<code>nrow</code>	number of rows used by "grid" method
<code>ncol</code>	number of columns used by "grid" method
<code>border.col</code>	border color used by "grid" method
<code>pt.cex</code>	point scaling factor used by "MDS" method
<code>pt.pch</code>	point symbol used by "MDS" method

### Details

Color sorting is based on CIE2000 distances as calculated by `farver::compare_colour()`. The "grid" method arranges colors in a rectangular grid with ordering based on divisive hierarchical clustering of the pair-wise distances. Unique colors are used when `cols` contains more than 5,000 colors.

The "MDS" method arranges unique colors via classical multidimensional scaling (principal coordinates) via `cmdscale()`.

Colors can be manually arranged by supplying a vector of integers to `col.order` and setting `method='manual'`.

**Value**

When method = "grid" or "manual" a vector of color order is returned. When method = "MDS", the output from MASS::cmdscale.

**Author(s)**

D.E. Beaudette

**Examples**

```
# example data
data(sp2)

# convert into SoilProfileCollection object
depths(sp2) <- id ~ top + bottom

previewColors(sp2$soil_color)
previewColors(sp2$soil_color, method = 'MDS', pt.cex = 3)

# create colors using HCL space
cols.hcl <- hcl(h = 0:360, c = 100, l = 50)

# grid, colors sorted by dE00
previewColors(cols.hcl)

# manual specification
previewColors(cols.hcl, method = 'manual', col.order = 1:361)

# MDS
previewColors(cols.hcl, method = 'MDS', pt.cex = 1)
```

prj,SoilProfileCollection-method

*Get or Set Coordinate Reference System for SoilProfileCollection*

---

**Description**

prj(): Get Coordinate Reference System (Projection) metadata  
 prj()<-: Set Coordinate Reference System metadata for the SoilProfileCollection  
 proj4string(): (Deprecated) Get Coordinate Reference System as PROJ4 String  
 proj4string()<-: (Deprecated) Set Coordinate Reference System metadata for the SoilProfileCollection

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
prj(object, ...)

## S4 replacement method for signature 'SoilProfileCollection'
prj(object, ...) <- value

## S4 method for signature 'SoilProfileCollection'
proj4string(obj)

## S4 replacement method for signature 'SoilProfileCollection,ANY'
proj4string(obj) <- value
```

**Arguments**

object	A SoilProfileCollection
...	Additional arguments (not used)
value	character. Representation of Coordinate Reference System as "authority:code", integer EPSG code, WKT2019 / PROJ4 string, an sf crs or sp CRS object.
obj	A SoilProfileCollection

**See Also**

[initSpatial<-\(\)](#)

---

profileApply	<i>Iterate over profiles in a SoilProfileCollection</i>
--------------	---

---

**Description**

Iterate over all profiles in a SoilProfileCollection, calling FUN on a single-profile SoilProfileCollection for each step.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
profileApply(
  object,
  FUN,
  simplify = TRUE,
  frameify = FALSE,
  chunk.size = 100,
  column.names = NULL,
  APPLY.FUN = lapply,
  ...
)
```

**Arguments**

object	a SoilProfileCollection
FUN	a function to be applied to each profile within the collection
simplify	logical, should the result be simplified to a vector? default: TRUE; see examples
frameify	logical, should the result be collapsed into a data.frame? default: FALSE; overrides simplify argument; see examples
chunk.size	numeric, size of "chunks" for faster processing of large SoilProfileCollection objects; default: 100
column.names	character, optional character vector to replace frameify-derived column names; should match length of colnames() from FUN result; default: NULL
APPLY.FUN	function, optional alternate lapply()-like function for processing chunks. For example <code>future.apply::future_lapply()</code> for processing chunks in parallel. Default <code>base::lapply()</code> .
...	additional arguments passed to FUN

**Value**

When `simplify` is TRUE, a vector of length `nrow(object)` (horizon data) or of length `length(object)` (site data). When `simplify` is FALSE, a list is returned. When `frameify` is TRUE, a data.frame is returned. An attempt is made to identify `idname` and/or `hzidname` in the data.frame result, safely ensuring that IDs are preserved to facilitate merging profileApply result downstream.

**Examples**

```
data(sp1)
depths(sp1) <- id ~ top + bottom

# estimate soil depth using horizon designations
profileApply(sp1, estimateSoilDepth, name='name')

# scale a single property 'prop' in horizon table
# scaled = (x - mean(x)) / sd(x)
sp1$d <- profileApply(sp1, FUN=function(x) round(scale(x$prop), 2))
plot(sp1, name='d')

# compute depth-wise differencing by profile
# note that our function expects that the column 'prop' exists
f <- function(x) { c(x$prop[1], diff(x$prop)) }
sp1$d <- profileApply(sp1, FUN=f)
plot(sp1, name='d')

# compute depth-wise cumulative sum by profile
# note the use of an anonymous function
sp1$d <- profileApply(sp1, FUN=function(x) cumsum(x$prop))
plot(sp1, name='d')

# compute profile-means, and save to @site
```

```

# there must be some data in @site for this to work
site(sp1) <- ~ group
sp1$mean_prop <- profileApply(sp1, FUN=function(x) mean(x$prop, na.rm=TRUE))

# re-plot using ranks defined by computed summaries (in @site)
plot(sp1, plot.order=rank(sp1$mean_prop))

## iterate over profiles, calculate on each horizon, merge into original SPC

# example data
data(sp1)

# promote to SoilProfileCollection
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

# calculate horizon thickness and proportional thickness
# returns a data.frame result with multiple attributes per horizon
thicknessFunction <- function(p) {
  hz <- horizons(p)
  depthnames <- horizonDepths(p)
  res <- data.frame(profile_id(p), hzID(p),
                    thk=(hz[[depthnames[[2]]]] - hz[[depthnames[1]]]))
  res$hz_prop <- res$thk / sum(res$thk)
  colnames(res) <- c(idname(p), hzidname(p), 'hz_thickness', 'hz_prop')
  return(res)
}

# list output option with simplify=F, list names are profile_id(sp1)
list.output <- profileApply(sp1, thicknessFunction, simplify = FALSE)
head(list.output)

# data.frame output option with frameify=TRUE
df.output <- profileApply(sp1, thicknessFunction, frameify = TRUE)
head(df.output)

# since df.output contains idname(sp1) and hzidname(sp1),
# it can safely be merged by a left-join via horizons<- setter
horizons(sp1) <- df.output

plot(density(sp1$hz_thickness, na.rm=TRUE), main="Density plot of Horizon Thickness")

## iterate over profiles, subsetting horizon data

# example data
data(sp1)

# promote to SoilProfileCollection
depths(sp1) <- id ~ top + bottom
site(sp1) <- ~ group

# make some fake site data related to a depth of some importance
sp1$dep <- profileApply(sp1, function(i) {round(rnorm(n=1, mean=mean(i$top)))})

```

```

# custom function for subsetting horizon data, by profile
# keep horizons with lower boundary < site-level attribute 'dep'
fun <- function(i) {
  # extract horizons
  h <- horizons(i)
  # make an expression to subset horizons
  exp <- paste('bottom < ', i$dep, sep='')

```

---

profileGroupLabels      *Soil Profile Group Labels*

---

## Description

Labels groups of soil profiles within soil profile sketches.

See examples below for ideas.

## Usage

```

profileGroupLabels(
  x0,
  x1,
  labels,
  y0 = 100,
  y1 = 98,
  label.offset = 2,
  label.cex = 0.75
)

```

**Arguments**

<code>x0</code>	integer indices to the first profile within each group
<code>x1</code>	integer indices to the last profile within each group
<code>labels</code>	vector of group labels
<code>y0</code>	baseline depth used for group brackets
<code>y1</code>	depth used for start and end markers for group brackets (see examples)
<code>label.offset</code>	vertical offset of group labels from baseline
<code>label.cex</code>	label size

**Note**

This function is typically called by some other convenience function such as [plotMultipleSPC](#).

**Author(s)**

D.E. Beaudette

**See Also**

[plotMultipleSPC](#)

**Examples**

```
# keep examples from using more than 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

# load sample data
data(sp3)
data(sp4)

# convert soil colors
sp3$h <- NA ; sp3$s <- NA ; sp3$v <- NA
sp3.rgb <- with(sp3, munsell2rgb(hue, value, chroma, return_triplets=TRUE))
sp3[, c('h','s','v')] <- t(with(sp3.rgb, rgb2hsv(r, g, b, maxColorValue=1)))

# promote to SoilProfileCollection
depths(sp3) <- id ~ top + bottom
depths(sp4) <- id ~ top + bottom

# combine into a list
spc.list <- list(sp3, sp4)

# compute group lengths and start/stop locations

group.starts <- c(1, 1 + cumsum(spc.lengths[-n.groups]))
group.ends <- cumsum(spc.lengths)
```

```

# determine depths of first / last profile in each group
yy <- unlist(sapply(spc.list, function(i) profileApply(i, max)))
tick.heights <- yy[c(group.starts, group.ends)] + 2

# plot 2 SoilProfileCollection objects on the same axis
par(mar=c(1,1,1,1))
plotSPC(sp3, n = n.pedons)
plotSPC(sp4, add = TRUE, x.idx.offset = group.ends[1],
depth.axis = FALSE, id.style = 'side')

# annotate groups
profileGroupLabels(x0 = group.starts, x1 = group.ends,
labels=c('Collection 1', 'Collection 2'), y0=120, y1=tick.heights)

```

---

profileInformationIndex

*Soil Profile Information Index*

---

## Description

A simple index of "information" content associated with individuals in a SoilProfileCollection object. Information content is quantified by number of bytes after compression via memCompress().

## Usage

```

profileInformationIndex(
  x,
  vars,
  method = c("joint", "individual"),
  baseline = FALSE,
  numericDigits = 8,
  padNA = FALSE,
  scaleNumeric = FALSE,
  compression = "gzip"
)

```

## Arguments

x	SoilProfileCollection object
vars	character vector of site or horizon level attributes to consider
method	character, 'individual' or 'joint' complexity
baseline	logical, compute ratio to "baseline" information content, see details
numericDigits	integer, number of significant digits to retain in numeric -> character conversion
padNA	logical, pad depths to max(x), supplied to dice(fill = padNA)

scaleNumeric	logical, scale() each numeric variable, causing "profile information" to vary based on other profiles in the collection
compression	character, compression method as used by <code>memCompress()</code> : 'gzip', 'bzip2', 'xz', 'none'

### Details

Information content via compression (gzip) is the central assumption behind this function: the values associated with a simple soil profile having few horizons and little variation between horizons (isotropic depth-functions) will compress to a much smaller size than a complex profile (many horizons, strong anisotropy). Information content is evaluated a profile at a time, over each site or horizon level attribute specified in vars. The `baseline` argument invokes a comparison to the simplest possible representation of each depth-function:

- `numeric`: replication of the mean value to match the number of horizons with non-NA values
- `character` or `factor`: replication of the most frequent value to match the number of horizons with non-NA values

The ratios computed against a "simple" baseline represent something like "information gain". Larger baseline ratios suggest more complexity (more information) associated with a soil profile's depth-functions. Alternatively, the total quantity of information (in bytes) can be determined by setting `baseline = FALSE`.

### Value

a numeric vector of the same length as `length(x)` and in the same order, suitable for direct assignment to a new site-level attribute

### Author(s)

D.E. Beaudette

### Examples

```
# single horizon, constant value
p1 <- data.frame(id = 1, top = 0, bottom = 100, p = 5, name = 'H')

# multiple horizons, constant value
p2 <- data.frame(
  id = 2, top = c(0, 10, 20, 30, 40, 50),
  bottom = c(10, 20, 30, 40, 50, 100),
  p = rep(5, times = 6),
  name = c('A1', 'A2', 'Bw', 'Bt1', 'Bt2', 'C')
)

# multiple horizons, random values
p3 <- data.frame(
  id = 3, top = c(0, 10, 20, 30, 40, 50),
  bottom = c(10, 20, 30, 40, 50, 100),
  p = c(1, 5, 10, 35, 6, 2),
```

```

  name = c('A1', 'A2', 'Bw', 'Bt1', 'Bt2', 'C')
)

# multiple horizons, mostly NA
p4 <- data.frame(
  id = 4, top = c(0, 10, 20, 30, 40, 50),
  bottom = c(10, 20, 30, 40, 50, 100),
  p = c(1, NA, NA, NA, NA, NA),
  name = c('A1', 'A2', 'Bw', 'Bt1', 'Bt2', 'C')
)

# shallower version of p1
p5 <- data.frame(id = 5, top = 0, bottom = 50, p = 5, name = 'H')

# combine and upgrade to SPC
z <- rbind(p1, p2, p3, p4, p5)
depths(z) <- id ~ top + bottom
hzdesgnname(z) <- 'name'

z <- fillHzGaps(z)

# visual check
par(mar = c(1, 0, 3, 3))
plotSPC(z, color = 'p', name.style = 'center-center', cex.names = 0.8, max.depth = 110)

# factor version of horizon name
z$name <- factor(z$name)

vars <- c('p', 'name')
# result is total bytes
pi <- profileInformationIndex(z, vars = vars, method = 'joint', baseline = FALSE)

text(x = 1:5, y = 105, labels = pi, cex = 0.85)
mtext('Profile Information Index (bytes)', side = 1, line = -1)

```

---

profile\_id<-

*Set profile IDs*

---

### Description

Set vector containing profile IDs

Get or set a vector of profile IDs

### Usage

```
## S4 replacement method for signature 'SoilProfileCollection'
profile_id(object) <- value
```

```
## S4 method for signature 'SoilProfileCollection'
profile_id(object)
```

**Arguments**

object	a SoilProfileCollection
value	a unique vector of equal length to number of profiles length(object)

quickSPC

*Quickly Assemble a SoilProfileCollection***Description**

Quickly assemble a single-profile, SoilProfileCollection object from two possible templates. This function is a useful shortcut for creating theoretical SoilProfileCollection objects for testing or demonstrative purposes.

**Usage**

```
quickSPC(
  x,
  id = "id",
  d = "depths",
  n = "name",
  m = "soil_color",
  interval = 10
)
```

**Arguments**

x	either a list or character vector, see Details and Examples
id	character, specified when x is a list, name of ID list element
d	character, specified when x is a list, name of depths list element
n	character, specified when x is a list, name of horizon name list element
m	character, specified when x is a list, name of list element containing Munsell color notation
interval,	numeric, typically an integer and only specified when using character templates in mode 2. See Details.

**Details**

The list template for a single SPC allows for full specification of ID, horizon designation, bottom depths, and an arbitrary number of horizon-level attributes. A compact notation is used for profile ID (single value) and horizon depths (bottom depths, assuming datum of 0). Horizon designation and additional data (e.g. clay content) are specified as vectors all of equal length, matching the number of horizons in the profile.

The character template can be provided in one of several formats:

1. 'A-Bt1-Bt2-Bt3-Cr-R'

2. 'ApAplAAIElBhsBhslBw1Bw1lCCCCC'

Format 1 is interpreted as a horizon sequence delimited by '-' or newline character (`\n`). Random integer thickness are assigned to horizons, and profile ID created via `digest::digest(..., algo = 'xxhash32')`. Iteration over templates in this format is automatic when `x` is a character vector of `length > 1`.

Format 2 is interpreted as a horizon sequence delimited by '|'. Horizon thickness is proportional to replication of horizon designation and scaled by the `interval` argument. Profile ID is created via `digest::digest(..., algo = 'xxhash32')`. Iteration over templates in this format is automatic when `x` is a character vector of `length > 1`.

Explicit naming of profile IDs can be accomplished by specifying an ID via prefix, as in "ID:A-Bt1-Bt2-Cr-R" or "ID:ApAplAAIElBhsBhslBw1Bw1lCCCCC". Labels specified before a ":" will be interpreted as a profile ID. These labels are optional but if specified must be unique within `x`.

Single-horizon profile templates must include a trailing horizon delimiter: '-', '\n', or '|' depending on the format.

## Value

SoilProfileCollection object

## Examples

```
# list-based template
x <- list(
  id = 'P1',
  depths = c(25, 33, 100, 150),
  name = c('A', 'Bw', 'Bt', 'Cr'),
  clay = c(12, 15, 22, 25),
  soil_color = c('10YR 3/3', '10YR 4/4', '10YR 4/6', '5G 6/2')
)

s <- quickSPC(x)
plotSPC(s, name.style = 'center-center', cex.names = 1)

# character template, mode 1
# horizon thickness is generated at random (uniform [5,20])
x <- 'A-Bt1-Bt2-Bt3-Cr-R'

        cex.names = 1, depth.axis = FALSE,
        hz.depths = TRUE)

```

---

random\_profile

*Random Profile*

---

## Description

Generate a random soil profile according to set criteria, with correlated depth trends.

The random walk method produces profiles with considerable variation between horizons and is based on values from the normal distribution seeded with means and standard deviations drawn from the uniform distribution of [0, 10].

The logistic power peak (LPP) function can be used to generate random soil property depth functions that are sharply peaked. LPP parameters can be hard-coded using the optional arguments: "lpp.a", "lpp.b", "lpp.u", "lpp.d", "lpp.e". Amplitude of the peak is controlled by ("lpp.a + "lpp.b"), depth of the peak by "lpp.u", and abruptness by "lpp.d" and "lpp.e". Further description of the method is outlined in (Brenton et al, 2011). Simulated horizon distinctness codes are based on the USDA-NCSS field description methods. Simulated distinctness codes are constrained according to

horizon thickness, i.e. a gradual boundary (+/- 5cm) will not be simulated for horizons that are thinner than 3x this vertical distance

### Usage

```
random_profile(
  id,
  n = c(3, 4, 5, 6),
  min_thick = 5,
  max_thick = 30,
  n_prop = 5,
  exact = FALSE,
  method = "random_walk",
  HzDistinctSim = FALSE,
  SPC = FALSE,
  ...
)
```

### Arguments

id	a character or numeric id used for this profile
n	vector of possible number of horizons, or the exact number of horizons (see below)
min_thick	minimum thickness criteria for a simulated horizon
max_thick	maximum thickness criteria for a simulated horizon
n_prop	number of simulated soil properties (columns in the returned dataframe)
exact	should the exact number of requested horizons be generated? (defaults to FALSE)
method	named method used to synthesize depth function ('random_walk' or 'LPP'), see details
HzDistinctSim	optionally simulate horizon boundary distinctness codes
SPC	result is a SoilProfileCollection object, otherwise a data.frame object
...	additional parameters passed-in to the LPP (.lpp) function

### Value

A data.frame or SoilProfileCollection object.

### Note

See examples for ideas on simulating several profiles at once.

### Author(s)

Dylan E. Beaudette

[checkSPC](#)

---

reduceSPC	<i>Select a subset of columns from a SoilProfileCollection</i>
-----------	--

---

### Description

Reduce the number of columns in a SoilProfileCollection to a minimal set plus additional selected columns. Optional metadata columns are included if set. At a minimum the profileID, horizon top and bottom depth, horizon ID are included. Horizon designation and horizon texture class column names are included if metadata attributes are set. See details.

### Usage

```
reduceSPC(p, column_names = NULL)
```

### Arguments

p	a SoilProfileCollection
column_names	a set of additional columns to include in the result

### Details

Minimum column names included (when column\_names = NULL)

- idname(p), horizonDepths(p), hzidname(p)

Optional column names included (when metadata are set)

- hzdesgname(p), hztexclname(p), GHl(p)

### Value

a SoilProfileCollection

### See Also

hzdesgname() hztexclname() GHl()

---

reorderHorizons	<i>Re-order corrupted horizon data</i>
-----------------	--

---

### Description

This is a method made available primarily to repair horizon data that have been corrupted relative to their order at time of SoilProfileCollection construction.

There is an option to specify the target order, but this will not update the corresponding metadata entry tracking the original order. Use this functionality at your own risk.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
reorderHorizons(object, target.order = NULL)
```

### Arguments

object	A SoilProfileCollection
target.order	A numeric vector of equal length to object. Default value is NULL which restores the internal order of the collection.

### Value

SoilProfileCollection

---

repairMissingHzDepths	<i>Repair Problematic Lower Horizon Depths</i>
-----------------------	--

---

### Description

Attempt a simple repair of horizon bottom depths in the presence of NA, or in cases where the horizon shares a common top and bottom depth. Both situations are common in pedon description where "contact" (Cd, Cr, R, etc.) was described without a lower depth.

### Usage

```
repairMissingHzDepths(x, adj = 10, max.depth = 200)
```

### Arguments

x	SoilProfileCollection
adj	vertical offset applied to "repair" missing bottom depths when top and bottom depth are equal or bottom depth is missing. (NA to use max.depth)
max.depth	If adj is NA, or the resulting offset sum exceeds max.depth, max.depth is used.

## Details

This repair is applied to the deepest horizon within a profile as identified by `getLastHorizonID`, as well as to bottom depths of any horizon that has a horizon below it. Horizon bottom depths are adjusted by adding `adj` (if non-NA). If the resulting value exceeds `max.depth`, the `max.depth` value is returned (if not NA).

## Value

SoilProfileCollection with a new (logical) horizon-level attribute `.repaired` marking affected horizons

## Examples

```
h <- data.frame(
  id = c(1, 1, 1, 2, 2, 2, 2, 3, 3),
  top = c(0:2, 0:3, 0:1) * 10,
  bottom = c(rep(NA_integer_, 7), c(10, 99))
)

# NA depths result in warnings
suppressWarnings({
  depths(h) <- id ~ top + bottom
})

# inspect data before repairs
plotSPC(h)

g <- repairMissingHzDepths(h)

# all depth logic now valid
all(checkHzDepthLogic(g)$valid)

# inspect
plotSPC(g)

# no adj, max.depth only
f <- repairMissingHzDepths(h, adj = NA, max.depth = 200)
all(checkHzDepthLogic(f)$valid)
plotSPC(f)

# max.depth defaults to max(x) if too small
f$bottom[c(3,7)] <- NA
d <- repairMissingHzDepths(f, adj = NA, max.depth = 20)
all(checkHzDepthLogic(d)$valid)
plotSPC(d)
```

---

replaceHorizons<-      *Replace Data in Horizon Slot*

---

### Description

Replaces horizon data with new data.frame object.

### Usage

```
## S4 replacement method for signature 'SoilProfileCollection'
replaceHorizons(object) <- value
```

### Arguments

object	A SoilProfileCollection
value	An object inheriting data.frame

### Examples

```
# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# one profile
p <- sp2[1,]

# 23 variables in horizon data
length(horizonNames(sp2))

# remove all but essential ones
replaceHorizons(p) <- horizons(p)[,c(idname(p),hgidname(p),horizonDepths(p))]

# inspect result (a clean slate)
horizons(p)
```

---

restrictions, SoilProfileCollection-method  
*Retrieve restriction data from SoilProfileCollection*

---

### Description

Get restriction data from SoilProfileCollection. Result is returned in the same data.frame class used to initially construct the SoilProfileCollection.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
restrictions(object)
```

**Arguments**

```
object          a SoilProfileCollection
```

---

```
restrictions<-      Add Data to Restrictions Slot
```

---

**Description**

Restrictions data in an object inheriting from `data.frame` can easily be added via `merge` (LEFT JOIN). There must be one or more same-named profile ID columns on the left and right hand side to facilitate the join: `restrictions(spc) <- newdata`.

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection'
restrictions(object) <- value
```

**Arguments**

```
object          A SoilProfileCollection
value           An object inheriting data.frame
```

**Examples**

```
# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# assign abrupt textural change to a profile

---

`rgb2munsell`*sRGB to Munsell Color Conversion*

---

### Description

Convert sRGB color coordinates to the closest *n* Munsell chips in the `munsell` lookup table. This function will be replaced by `col2Munsell()` in **aqp 2.1**.

### Usage

```
rgb2munsell(color, colorSpace = c("CIE2000", "LAB", "sRGB"), nClosest = 1)
```

### Arguments

<code>color</code>	a <code>data.frame</code> or <code>matrix</code> object containing sRGB coordinates in the range of (0,1)
<code>colorSpace</code>	distance metric (colorspace) to use for finding the closest chip: CIE2000 is the most accurate but requires <code>farver &gt;= 2.0.3</code> , Euclidean distance in CIELAB is a close second, while Euclidean distance in sRGB is not at all accurate and should only be used for demonstration purposes.
<code>nClosest</code>	number of closest Munsell colors to return (valid range is 1-20)

### Value

an (NA-padded) `data.frame` containing hue, value, chroma, and distance (dE00 when `colorSpace = 'CIE2000'`, Euclidean distance otherwise) to nearest matching color.

### Note

This function is fully vectorized and will pad output with NA-records when NA are present in `color`.

### Author(s)

D.E. Beaudette

### References

## Examples

```
# keep examples from using more than 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

# Munsell notation to sRGB triplets [0-1]
color <- munsell2rgb(
  the_hue = c('10YR', '2.5YR', '5YR'),
  the_value = c(3, 5, 2.5),
  the_chroma = c(5, 6, 2),
  return_triplets = TRUE
)

# result is a data.frame
color

# back-transform sRGB -> closest Munsell color
# sigma is the dE00 color contrast metric
rgb2munsell(color)
```

ROSETTA.centroids	<i>Average Hydraulic Parameters from the ROSETTA Model by USDA Soil Texture Class</i>
-------------------	---

---

## Description

Average soil hydraulic parameters generated by the first stage predictions of the ROSETTA model by USDA soil texture class. These data were extracted from [ROSETTA documentation](#) and reformatted for ease of use.

## Usage

```
data(ROSETTA.centroids)
```

## Format

A data frame:

**texture** soil texture class, ordered from low to high available water holding capacity

**theta\_r** average saturated water content

**theta\_s** average residual water content

**alpha** average value, related to the inverse of the air entry suction, log10-transformed values with units of cm

**npar** average value, index of pore size distribution, log10-transformed values with units of 1/cm

**theta\_r\_sd** 1 standard deviation of theta\_r

**theta\_s\_sd** 1 standard deviation of theta\_s

**alpha\_sd** 1 standard deviation of alpha  
**npar\_sd** 1 standard deviation of npar  
**sat** approximate volumetric water content at which soil material is saturated  
**fc** approximate volumetric water content at which matrix potential = -33kPa  
**pwp** approximate volumetric water content at which matrix potential = -1500kPa  
**awc** approximate available water holding capacity: VWC(-33kPa)
 

- VWC(-1500kPa)

### Details

Theoretical water-retention parameters for uniform soil material of each texture class have been estimated via van Genuchten model.

See [the related tutorial](#)

---

SANN\_1D

*Fix Overlap within a Sequence via Simulated Annealing*

---

### Description

This function makes small adjustments to elements of  $x$  until overlap defined by `thresh` is removed, or until `maxIter` is reached. Rank order and boundary conditions (defined by `min.x` and `max.x`) are preserved. The underlying algorithm is based on simulated annealing. The "cooling schedule" parameters  $T_0$  and  $k$  can be used to tune the algorithm for specific applications.

### Usage

```

SANN_1D(
  x,
  thresh = 0.6,
  adj = thresh * 2/3,
  min.x = min(x) - 0.2,
  max.x = max(x) + 0.2,
  maxIter = 1000,
  trace = FALSE,
  tiny = 1e-04,
  T0 = 500,
  k = 10,
  ...
)

```

### Arguments

<code>x</code>	vector of horizontal positions, pre-sorted
<code>thresh</code>	horizontal threshold defining "overlap" or distance between elements of $x$ . For adjusting soil profile sketches values are typically $< 1$ and likely in (0.3, 0.8).

<code>adj</code>	specifies the size of perturbations within <code>runif(min = adj * -1, max = adj)</code> . Larger values will sometimes reduce the number of iterations required to solve particularly difficult overlap conditions. See <code>coolingRate</code> argument when <code>adj</code> is large
<code>min.x</code>	left-side boundary condition, consider expanding if a solution cannot be found within <code>maxIter</code> .
<code>max.x</code>	right-side boundary condition, consider expanding if a solution cannot be found within <code>maxIter</code> .
<code>maxIter</code>	maximum number of iterations to attempt before giving up and returning a regularly-spaced sequence
<code>trace</code>	print diagnostics, result is a list vs vector
<code>tiny</code>	the smallest allowable overlap
<code>T0</code>	starting temperature
<code>k</code>	cooling constant
<code>...</code>	not used, absorbs additional arguments to <code>fixOverlap()</code>

### Details

Ideas for solving difficult overlap scenarios:

- widen the boundary conditions by adjusting `min.x` and `max.x` beyond the original scale of `x`
- reduce the allowable overlap threshold `thresh`
- reduce the magnitude of perturbations (`adj`) and increase `maxIter`
- increase `k`

### Value

When `trace = FALSE`, a vector of the same length as `x`, preserving rank-ordering and boundary conditions. When `trace = TRUE` a list containing the new sequence along with information about objective functions and decisions made during iteration.

### Examples

```
x <- c(1, 2, 3, 3.4, 3.5, 5, 6, 10)

# easy
z <- fixOverlap(x, thresh = 0.2, trace = TRUE)
```

```

# harder
z <- fixOverlap(x, thresh = 0.6, trace = TRUE)

# much harder
z <- fixOverlap(x, thresh = 0.9, trace = TRUE)

# interpret `trace` output

# relatively challenging
x <- c(1, 2, 3.4, 3.4, 3.4, 3.4, 6, 8, 10, 12, 13, 13, 15, 15.5)

# fix overlap, return debugging information
set.seed(10101)
z <- fixOverlap(x, thresh = 0.8, trace = TRUE)

# setup plot device
par(mar = c(4, 4, 1, 1))
layout(matrix(c(1,2,3)), widths = 1, heights = c(1,1,2))

# objective function = overlap + SSD
plot(
  seq_along(z$stats), z$stats,
  type = 'h', las = 1,
  xlab = 'Iteration', ylab = 'Overlap',
  cex.axis = 0.8
)

# SSD: deviation from original configuration
plot(
  seq_along(z$ssd), z$ssd,
  type = 'h', las = 1,
  xlab = 'Iteration', ylab = 'Deviation',
  cex.axis = 0.8
)

# adjustments at each iteration
matplot(
  z$states, type = 'l',
  lty = 1, las = 1,
  xlab = 'Iteration', ylab = 'x-position'
)

# trace log
# B: boundary condition violation
# O: rank (order) violation
# +: accepted perturbation
# -: rejected perturbation
table(z$log)

```

## Description

This function segments or subdivides horizon data from a `SoilProfileCollection` or `data.frame` by depth interval (e.g. `c(0, 10)`, `c(0, 50)`, or `25:100`). This results in horizon records being split at the specified depth intervals, which duplicates the original horizon data but also adds new horizon depths. In addition, labels (i.e. `"segment_id"`) are added to each horizon record that correspond with their depth interval (e.g. `025-100`). This function is intended to harmonize horizons to a common support (i.e. depth interval) for further aggregation or summary. See the examples.

## Usage

```
segment(object, intervals, trim = TRUE, hzdepcols = NULL)
```

## Arguments

<code>object</code>	either a <code>SoilProfileCollection</code> or <code>data.frame</code>
<code>intervals</code>	a vector of integers over which to slice the horizon data (e.g. <code>c(25, 100)</code> or <code>25:100</code> )
<code>trim</code>	logical, when <code>TRUE</code> horizons in <code>object</code> are truncated to the min/max specified in <code>intervals</code> . When <code>FALSE</code> , those horizons overlapping an interval are marked as such. Care should be taken when specifying more than one depth interval and <code>trim = FALSE</code> .
<code>hzdepcols</code>	a character vector of length 2 specifying the names of the horizon depths (e.g. <code>c("hzdept", "hzdepb")</code> ), only necessary if <code>object</code> is a <code>data.frame</code> .

## Details

`segment()` performs no aggregation or resampling of the source data, rather, labels are added to horizon records for subsequent aggregation or summary. This makes it possible to process a very large number of records outside of the constraints associated with e.g. `slice()` or `slab()`.

## Value

Either a `SoilProfileCollection` or `data.frame` with the original horizon data segmented by depth intervals. There are usually more records in the resulting object, one for each time a segment interval partially overlaps with a horizon. A new column called `segment_id` identifying the depth interval is added.

---

shannonEntropy

*Shannon Entropy*

---

### Description

A very simple implementation of Shannon entropy.

### Usage

```
shannonEntropy(x, b = 2)
```

### Arguments

x	vector of probabilities (0,1), must sum to 1, should not contain NA
b	logarithm base

**Details**

0s are automatically removed by `na.rm = TRUE`, as  $(0 * \log(0) = \text{NaN})$

**Value**

A single numeric value.

**Note**

When `b = length(x)` the result is the normalized Shannon entropy of (Kempen et al, 2009).

**References**

sim

---

*DEPRECATED Simulate Soil Profiles*

---

## Description

Simulate a collection of soil profiles based on the horizonation of a single soil profile. Now deprecated: use [perturb\(\)](#) for perturbations of horizon thicknesses or boundaries.

## Usage

```
sim(x, n = 1, iterations = 25, hz.sd = 2, min.thick = 2)
```

## Arguments

x	a SoilProfileCollection object containing a single profile from which to draw simulated data
n	the number of requested simulations
iterations	sampling iterations used to determine each horizon thickness
hz.sd	standard deviation used to simulate horizon thickness, can be a vector but must divide evenly into the number of horizons found in x
min.thick	minimum horizon thickness allowed in simulation results

## Details

This function generates a collection of simulated soil profiles based on the horizon thickness data associated with a single "template" profile. Simulation is based on sampling from a family of Gaussian distribution with means defined by the "template" profile and standard deviation defined by the user.

**Value**

A SoilProfileCollection object with n simulated profiles, each containing the same number of horizons and same data as x

**Author(s)**

D. E. Beaudette

**See Also**

[random\\_profile](#) [perturb](#)

**Examples**

```
# please see documentation for perturb() for examples
# the sim() function calls perturb() internally
```

---

simulateColor

*Simulate Soil Colors*

---

**Description**

Simulate plausible soil colors based on proportions by Munsell "chip", or using a seed Munsell chip and threshold specified via CIE2000 color contrast metric.

**Usage**

```
simulateColor(method = c("dE00", "proportions"), n, parameters, SPC = NULL)
```

**Arguments**

method	simulation method, see details
n	number of simulated colors per horizon
parameters	a list, format depends on method: <ul style="list-style-type: none"> <li>proportions: output from <a href="#">aggregateColor</a></li> <li>dE00: formatted as <code>list(m = '7.5YR 3/3', thresh = 5, hues = c('7.5YR'))</code></li> </ul> Where m is a single representative Munsell chip, thresh is a threshold specified in CIE2000 color contrast (dE00), and hues is a vector of allowed Munsell hues.
SPC	SoilProfileCollection, attempt to modify SPC with simulated colors

**Value**

a list, unless SPC is specified, then a SoilProfileCollection object

**Author(s)**

D.E. Beaudette

**Examples**

```
# restrict examples to 2 cores
data.table::setDTthreads(Sys.getenv("OMP_THREAD_LIMIT", unset = 2))

# m: representative or most likely color
# thresh: dE00 threshold

```

---

```
site,SoilProfileCollection-method
```

*Retrieve site data from SoilProfileCollection*

---

### Description

Get site data from SoilProfileCollection. Result is returned in the same data.frame class used to initially construct the SoilProfileCollection.

There are two options available via the site<- setter.

The first is a "normalization" by formula interface, whereby one specifies an attribute that is constant in horizons within profiles to be promoted to a site-level variable: site(spc) <- ~ horizonvariable

The second is creation of site data from an external data.frame via merge (LEFT JOIN). There must be one or more same-named columns (with at least some matching data) on the left and right hand side to facilitate the join: site(spc) <- newdata

### Usage

```
## S4 method for signature 'SoilProfileCollection'
site(object)

site(object) <- value
```

### Arguments

object	A SoilProfileCollection
value	A formula or object inheriting data.frame

### Examples

```
# load test data
data(sp2)

# promote to SPC
depths(sp2) <- id ~ top + bottom

# normalize a horizon-level attribute to site
site(sp2) <- ~ surface

# inspect site table
site(sp2)

# make some data: classify two geomorphic surfaces with numeric value
newdata <- data.frame(surface = c("holocene",
                                "lower riverbank"),
                      newvalue = c(1,2))
```

```
# do left join based on newly-normalized "surface" attribute
site(sp2) <- newdata

# inspect site table: holocene & lower riverbank have values
site(sp2)
```

---

```
siteNames<-          Set site column names
```

---

### Description

Set site column names  
 Get names of columns in site table.

### Usage

```
## S4 replacement method for signature 'SoilProfileCollection'
siteNames(object) <- value

## S4 method for signature 'SoilProfileCollection'
siteNames(object)
```

### Arguments

object	a SoilProfileCollection
value	a unique vector of equal length to number of columns in site: length(siteNames(object))

---

```
slab          Slab-Wise Aggregation of SoilProfileCollection Objects
```

---

### Description

Aggregate soil properties along user-defined slabs, and optionally within groups.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
slab(
  object,
  fm,
  slab.structure = 1,
  strict = FALSE,
  byhz = TRUE,
  slab.fun = slab_function(method = "numeric"),
  cpm = 1,
```

```

    weights = NULL,
    ...
)

slab_function(
  method = c("numeric", "factor", "hd", "weighted.numeric", "weighted.factor", "fast")
)

```

### Arguments

<code>object</code>	a <code>SoilProfileCollection</code>
<code>fm</code>	A formula: either <code>groups ~ var1 + var2 + var3</code> where named variables are aggregated within groups' OR where named variables are aggregated across the entire collection <code>var1 + var2 + var3</code> . If <code>groups</code> is a factor it must not contain NA'
<code>slab.structure</code>	A user-defined slab thickness (defined by an integer), or user-defined structure (numeric vector). See details below.
<code>strict</code>	logical: should horizons be strictly checked for self-consistency?
<code>byhz</code>	logical: should horizons or whole profiles be removed by logic checks in <code>strict</code> ? Default TRUE removes only offending horizons, FALSE removes whole profiles with one or more illogical horizons.
<code>slab.fun</code>	Function used to process each 'slab' of data, ideally returning a vector with names attribute. Defaults to a wrapper function around <code>stats::quantile()</code> . See details.
<code>cpm</code>	Strategy for normalizing slice-wise probabilities, dividing by either: number of profiles with data at the current slice ( <code>cpm=1</code> ), or by the number of profiles in the collection ( <code>cpm=2</code> ). Mode 1 values will always sum to the contributing fraction, while mode 2 values will always sum to 1.
<code>weights</code>	Column name containing site-level weights
<code>...</code>	further arguments passed to <code>slab.fun</code>
<code>method</code>	one of "numeric", "factor", "hd", "weighted.numeric", "weighted.factor", "fast"

### Details

Multiple continuous variables OR a single categorical (factor) variable can be aggregated within a call to `slab`. Basic error checking is performed to make sure that top and bottom horizon boundaries make sense. User-defined aggregate functions (`slab.fun`) should return a named vector of results. A new, named column will appear in the results of `slab` for every named element of a vector returned by `slab.fun`. See examples below for a simple example of a slab function that computes mean, mean-1SD and mean+1SD. The default slab function wraps `stats::quantile` from the `Hmisc` package, which requires at least 2 observations per chunk. Note that if `group` is a factor it must not contain NAs.

`slab()` uses `dice()` to "resample" profiles to 1cm slices from depth 0 to `max(x)` (or `slab.structure[2]`, if defined).

Sometimes `slab` is used to conveniently re-arrange data vs. `aggregate`. This is performed by specifying `identity` in `slab.fun`. See examples below for a demonstration of this functionality.

The default `slab.fun` was changed 2019-10-30 from a wrapper around `Hmisc::hdquantile` to a wrapper around `stats::quantile`. See examples below for a simple way to switch to the HD quantile estimator.

Execution time scales linearly (slower) with the total number of profiles in object, and exponentially (faster) as the number of profiles / group is increased. `slab` and `slice` are much faster and require less memory if input data are either numeric or character.

There are several possible ways to define slabs, using `slab.structure`:

**a single integer** e.g. 10: data are aggregated over a regular sequence of 10-unit thickness slabs

**a vector of 2 integers** e.g. `c(50, 60)`: data are aggregated over depths spanning 50–60 units

**a vector of 3 or more integers** e.g. `c(0, 5, 10, 50, 100)`: data are aggregated over the depths spanning 0–5, 5–10, 10–50, 50–100 units

`slab_function()`: The default "numeric" aggregation method is the "fast" numeric (quantile) method. Additional methods include "factor" for categorical data, "hd" to use the Harrell-Davis Distribution-Free Quantile Estimator from the Hmisc package, and "weighted" to use a weighted quantile method from the Hmisc package

## Value

Output is returned in long format, such that slice-wise aggregates are returned once for each combination of grouping level (optional), variable described in the `fm` argument, and depth-wise 'slab'.

Aggregation of numeric variables, using the default slab function:

**variable** The names of variables included in the call to `slab`.

**groupname** The name of the grouping variable when provided, otherwise a fake grouping variable named 'all.profiles'.

**p.q5** The slice-wise 5th percentile.

**p.q25** The slice-wise 25th percentile

**p.q50** The slice-wise 50th percentile (median)

**p.q75** The slice-wise 75th percentile

**p.q95** The slice-wise 95th percentile

**top** The slab top boundary.

**bottom** The slab bottom boundary.

**contributing\_fraction** The fraction of profiles contributing to the aggregate value, ranges from  $1/n_{\text{profiles}}$  to 1.

When a single factor variable is used, slice-wise probabilities for each level of that factor are returned as:

**variable** The names of variables included in the call to `slab`.

**groupname** The name of the grouping variable when provided, otherwise a fake grouping variable named 'all.profiles'.

**A** The slice-wise probability of level A

**B** The slice-wise probability of level B

**list()**

**n** The slice-wise probability of level n

**top** The slab top boundary.

**bottom** The slab bottom boundary.

**contributing\_fraction** The fraction of profiles contributing to the aggregate value, ranges from  $1/n_{\text{profiles}}$  to 1.

`slab_function()`: return an aggregation function based on the method argument

**Methods**

**data = "SoilProfileCollection"** Typical usage, where input is a [SoilProfileCollection](#).

**Note**

Arguments to `slab` have changed with aqp 1.5 (2012-12-29) as part of a code clean-up and optimization. Calculation of weighted-summaries was broken in aqp 1.2-6 (2012-06-26), and removed as of aqp 1.5 (2012-12-29). `slab` replaced the previously defined `soil.slot.multiple` function as of aqp 0.98-8.58 (2011-12-21).

## End(Not run)

```

**Description**

A method for "slicing" of SoilProfileCollection objects into constant depth intervals. Now deprecated, see [dice()].

**Usage**

```
slice.fast(object, fm, top.down = TRUE, just.the.data = FALSE, strict = TRUE)

## S4 method for signature 'SoilProfileCollection'
slice(object, fm, top.down = TRUE, just.the.data = FALSE, strict = TRUE)

get.slice(h, id, top, bottom, vars, z, include = "top", strict = TRUE)
```

**Arguments**

object	a SoilProfileCollection
fm	A formula: either integer.vector ~ var1 + var2 + var3 where named variables are sliced according to integer.vector OR where all variables are sliced according to integer.vector: integer.vector ~ ..
top.down	logical, slices are defined from the top-down: 0:10 implies 0-11 depth units.
just.the.data	Logical, return just the sliced data or a new SoilProfileCollection object.
strict	Check for logic errors? Default: TRUE
h	Horizon data.frame
id	Profile ID
top	Top Depth Column Name
bottom	Bottom Depth Column Name
vars	Variables of Interest
z	Slice Depth (index).
include	Either 'top' or 'bottom'. Boundary to include in slice. Default: 'top'

**Value**

Either a new SoilProfileCollection with data sliced according to fm, or a data.frame.

**Details**

By default, slices are defined from the top-down: 0:10 implies 0-11 depth units.

slicedHSD

*Tukey's HSD Over Slices*

---

### Description

Apply Tukey's HSD over 1-unit depth slices.

### Usage

```
slicedHSD(object, fm, conf = 0.95)
```

### Arguments

object	SoilProfileCollection object
fm	a formula describing depth sequence, horizon attribute, and site (grouping) attribute. For example 0:100 ~ estimated_oc   taxonname
conf	confidence applied in TukeyHSD

### Author(s)

D.E. Beaudette and Sharon Perrone

---

 soilColorSignature      *Soil Profile Color Signatures*

---

## Description

Generate a color signature for each soil profile in a collection.

## Usage

```
soilColorSignature(
  spc,
  r = "r",
  g = "g",
  b = "b",
  method = c("colorBucket", "depthSlices", "pam"),
  pam.k = 3,
  RescaleLightnessBy = 1,
  useProportions = TRUE,
  pigmentNames = c(".white.pigment", ".red.pigment", ".green.pigment", ".yellow.pigment",
    ".blue.pigment"),
  apply.fun = lapply
)
```

## Arguments

spc	a SoilProfileCollection object
r	horizon level attribute containing soil color (sRGB) red values
g	horizon level attribute containing soil color (sRGB) green values
b	horizon level attribute containing soil color (sRGB) blue values
method	algorithm used to compute color signature, colorBucket, depthSlices, or pam
pam.k	number of classes to request from cluster::pam()
RescaleLightnessBy	rescaling factor for CIE LAB L-coordinate
useProportions	use proportions or quantities, see details
pigmentNames	names for resulting pigment proportions or quantities
apply.fun	function passed to aqp::profileApply(APPLY.FUN) argument, can be used to add progress bars via pbapply::pblapply, or parallel processing with furrr::future_map

## Details

See the [related tutorial](#).

**Value**

For the `colorBucket` method, a `data.frame` object containing:

- `id` column: set according to `idname(spc)`
- `.white.pigment`: proportion or quantity of CIE LAB L-values
- `.red.pigment`: proportion or quantity of CIE LAB positive A-values
- `.green.pigment`: proportion or quantity of CIE LAB negative A-values
- `.yellow.pigment`: proportion or quantity of CIE LAB positive B-values
- `.blue.pigment`: proportion or quantity of CIE LAB negative B-values

Column names can be adjusted with the `pigmentNames` argument.

For the `depthSlices` method ...

For the `pam` method ...

**Examples**

```
# trivial example, not very interesting
data(sp1)
depths(sp1) <- id ~ top + bottom

# convert Munsell -> sRGB triplets
rgb.data <- munsell2rgb(sp1$hue, sp1$value, sp1$chroma, return_triplets = TRUE)
sp1$r <- rgb.data$r
sp1$g <- rgb.data$g
sp1$b <- rgb.data$b

# extract color signature
pig <- soilColorSignature(sp1)
```

---

`soilPalette`*Soil Color Palette*

---

**Description**

A very simple function for generating labeled swatches of soil colors. Largely based on `colorspace::swatchplot`.

**Usage**

```
soilPalette(  
  colors,  
  lab = colors,  
  lab.cex = 0.75,  
  dynamic.labels = TRUE,  
  x.inset = 0.01,  
  y.inset = 0.01,  
  ...  
)
```

**Arguments**

<code>colors</code>	vector of hex colors (e.g. #A66E46FF)
<code>lab</code>	vector of labels
<code>lab.cex</code>	character scaling for labels
<code>dynamic.labels</code>	logical, adjust label colors for maximum contrast via <code>invertLabelColor</code>
<code>x.inset</code>	horizontal adjustment for labels
<code>y.inset</code>	vertical adjustment for labels
<code>...</code>	further arguments to <code>colorspace::swatchplot</code>

**Note**

The result is a simple figure on the active plotting device.

**Author(s)**

D.E. Beaudette

**Examples**

```
# maybe useful for teaching about soil color  
  
par(mfrow=c(2,1), mar=c(1,1,1,1))  
  
# demonstrate range of Munsell value  
m <- sprintf('10YR %s/4', 2:8)
```

```

# convert to hex representation
cols <- parseMunsell(m)
# plot
soilPalette(cols, m)

# demonstrate range of Munsell chroma
m <- sprintf('10YR 4/%s', 2:8)
# convert to hex representation
cols <- parseMunsell(m)
# plot
soilPalette(cols, m)

```

---

SoilProfileCollection *An S4 object representation of a group of soil profiles.*

---

## Description

In general, one should use `depths()` to initiate a `SoilProfileCollection` object from data. However, sometimes there are instances where either an empty, or very specific, object is needed. If that is the case, the general constructor `SoilProfileCollection` is available.

## Usage

```

SoilProfileCollection(
  idcol = "id",
  hzidcol = "hzID",
  depthcols = c("top", "bottom"),
  metadata = list(aqp_df_class = "data.frame", aqp_group_by = "", aqp_hzdesgn = "",
    aqp_hztexcl = "", stringsAsFactors = FALSE),
  horizons = data.frame(id = character(0), hzID = character(0), top = numeric(0), bottom
    = numeric(0), stringsAsFactors = FALSE),
  site = data.frame(id = character(0), stringsAsFactors = FALSE),
  sp = new("SpatialPoints"),
  diagnostic = data.frame(stringsAsFactors = FALSE),
  restrictions = data.frame(stringsAsFactors = FALSE)
)

```

## Arguments

<code>idcol</code>	character Profile ID Column Name
<code>hzidcol</code>	character Horizon ID Column Name
<code>depthcols</code>	character, length 2 Top and Bottom Depth Column Names
<code>metadata</code>	list, metadata including data.frame class in use and depth units
<code>horizons</code>	data.frame An object inheriting from data.frame containing Horizon data.
<code>site</code>	data.frame An object inheriting from data.frame containing Site data.

sp	SpatialPoints A SpatialPoints object. No longer used in aqp 2+, see ?initSpatial
diagnostic	data.frame An object inheriting from data.frame containing diagnostic feature data. Must contain profile ID. See diagnostic_hz()
restrictions	data.frame An object inheriting from data.frame containing restrictive feature data. Must contain profile ID. See restrictions()

**Slots**

idcol character.  
 hzidcol character.  
 depthcols character.  
 metadata list.  
 horizons data.frame.  
 site data.frame.  
 sp SpatialPoints.  
 diagnostic data.frame.  
 restrictions data.frame.

horizonDepths(sp1)

# edit profile IDs
p <- sprintf("%s-new", profile_id(sp1))
profile_id(sp1) <- p
profile_id(sp1)
```

---

soiltexture

*Lookup tables for sand, silt, clay, texture class, and textural modifiers.*

---

### Description

A list that contains a snapshot of the values generated using the logic from the particle size estimator calculation in NASIS, the average values per texture class, and average rock fragment values by textural modifier.

A list that contains a snapshot of the values generated using the logic from the particle size estimator calculation in NASIS, the average values per texture class, and average rock fragment values by textural modifier.

### Format

A list with 3 data frames. The first named values which contains values for sand, silt and clay by texture class. The second with average values for sand, silt and clay per texture class. The third has fragvoltot low, rv and high values for texmod.

**list("clay")** clay percentage of the fine earth fraction, a integer vector

**list("sand")** sand percentage of the fine earth fraction, a integer vector

**list("silt")** silt percentage of the fine earth fraction, a integer vector

**list("texcl")** texture class, a character vector

**list("texmod")** textural modifiers, a character vector

SoilTextureLevels      *Ranking Systems for USDA Soil Texture Classes*

---

**Description**

Generate a vector of USDA soil texture codes or class names, sorted according to approximate particle size

**Usage**

```
SoilTextureLevels(which = "codes", simplify = FALSE)
```

**Arguments**

which	'codes' (texture codes) or 'names' (texture class names)
simplify	Return 12-class factor levels (TRUE) or 21-class factor levels (default: FALSE)? The 12-class system does not separate sands, loamy sands and sandy loams into sand fraction variants (e.g. "very fine sandy loam" in the 21-class system is "sandy loam" in 12-class system)

**Value**

an ordered factor

**References**

[Field Book for Describing and Sampling Soils, version 3.0](#)

**Examples**

```
# class codes
SoilTextureLevels()

# class names
SoilTextureLevels(which = 'names')

# simpler class names
SoilTextureLevels(which = 'names', simplify = TRUE)
```

---

`soil_minerals`*Munsell Colors of Common Soil Minerals*

---

**Description**

Munsell colors for some common soil minerals.

**Usage**

```
data(soil_minerals)
```

**Format**

A data frame with 20 observations on the following 5 variables.

**mineral** mineral name

**color** Munsell color

**hue** Munsell hue

**value** Munsell value

**chroma** Munsell chroma

**Details**

Soil color and other properties including texture, structure, and consistence are used to distinguish and identify soil horizons (layers) and to group soils according to the soil classification system called Soil Taxonomy. Color development and distribution of color within a soil profile are part of weathering. As rocks containing iron or manganese weather, the elements oxidize. Iron forms small crystals with a yellow or red color, organic matter decomposes into black humus, and manganese forms black mineral deposits. These pigments paint the soil (Michigan State Soil). Color is also affected by the environment: aerobic environments produce sweeping vistas of uniform or subtly changing color, and anaerobic (lacking oxygen), wet environments disrupt color flow with complex, often intriguing patterns and points of accent. With depth below the soil surface, colors usually become lighter, yellower, or redder.

*Soil Profile Data Example 1*

---

### Description

Soil profile data from Pinnacles National Monument, CA.

### Format

A data frame with 60 observations on the following 21 variables.

**group** a numeric vector

**id** a character vector  
**top** a numeric vector  
**bottom** a numeric vector  
**bound\_distinct** a character vector  
**bound\_topography** a character vector  
**name** a character vector  
**texture** a character vector  
**prop** a numeric vector  
**structure\_grade** a character vector  
**structure\_size** a character vector  
**structure\_type** a character vector  
**stickiness** a character vector  
**plasticity** a character vector  
**field\_ph** a numeric vector  
**hue** a character vector  
**value** a numeric vector  
**chroma** a numeric vector

*Honcut Creek Soil Profile Data*

### Description

A collection of 18 soil profiles, consisting of select soil morphologic attributes, associated with a stratigraphic study conducted near Honcut Creek, California.

### Format

A data frame with 154 observations on the following 21 variables.

**id** profile id  
**surface** dated surface  
**top** horizon top in cm  
**bottom** horizon bottom in cm  
**bound\_distinct** horizon lower boundary distinctness class  
**bound\_topography** horizon lower boundary topography class  
**name** horizon name  
**texture** USDA soil texture class  
**prop** field-estimated clay content  
**structure\_grade** soil structure grade  
**structure\_size** soil structure size  
**structure\_type** soil structure type  
**stickiness** stickiness  
**plasticity** plasticity  
**field\_ph** field-measured pH  
**hue** Munsell hue  
**value** Munsell value  
**chroma** Munsell chroma  
**r** RGB red component  
**g** RGB green component  
**b** RGB blue component  
**soil\_color** R-friendly encoding of soil color

*Soil Profile Data Example 3*

---

**Description**

Soil samples from 10 soil profiles, taken from the Sierra Foothill Region of California.

**Format**

A data frame with 46 observations on the following 15 variables.

**id** soil id  
**top** horizon upper boundary (cm)  
**bottom** horizon lower boundary (cm)  
**clay** clay content  
**cec** CEC by amonium acetate at pH 7  
**ph** pH in 1:1 water-soil mixture  
**tc** total carbon percent  
**hue** Munsell hue (dry)  
**value** Munsell value (dry)  
**chroma** Munsell chroma (dry)  
**mid** horizon midpoint (cm)  
**ln\_tc** natural log of total carbon percent  
**L** color: l-coordinate, CIE-LAB colorspace (dry)  
**A** color: a-coordinate, CIE-LAB colorspace (dry)  
**B** color: b-coordinate, CIE-LAB colorspace (dry)  
**name** horizon name  
**soil\_color** horizon color

**Details**

These data were collected to support research funded by the Kearney Foundation of Soil Science.

*Soil Chemical Data from Serpentinic Soils of California*

---

### Description

Soil Chemical Data from Serpentinic Soils of California

### Format

A data frame with 30 observations on the following 13 variables.

**id** site name

**name** horizon designation

**top** horizon top boundary in cm

**bottom** horizon bottom boundary in cm

**K** exchangeable K in c mol/kg

**Mg** exchangeable Mg in cmol/kg

**Ca** exchangeable Ca in cmol/kg

**CEC\_7** cation exchange capacity (NH<sub>4</sub>OAc at pH 7)

**ex\_Ca\_to\_Mg** extractable Ca:Mg ratio

**sand** sand content by weight percentage

**silt** silt content by weight percentage

**clay** clay content by weight percentage

**CF** >2mm fraction by volume percentage

### Details

Selected soil physical and chemical data from (McGahan et al., 2009).

*Soil Physical and Chemical Data from Manganiferous Soils*

---

## Description

Soil Physical and Chemical Data from Manganiferous Soils (Bourgault and Rabenhorst, 2011)

## Format

A data frame with 30 observations on the following 13 variables.

**id** pedon name  
**name** horizon designation  
**top** horizon top boundary in cm  
**bottom** horizon bottom boundary in cm  
**color** moist soil color in Munsell notation  
**texture** USDA soil texture class  
**sand** sand content by weight percentage  
**silt** silt content by weight percentage  
**clay** clay content by weight percentage  
**Fe** DCB-extracted Fe in g/kg (see citation)  
**Mn** DCB-extracted Mn in g/kg (see citation)  
**C** total organic carbon as g/kg  
**pH** measured in 1:1 H<sub>2</sub>O slurry  
**Db** bulk density (g/cc), clod method

**Details**

Selected soil physical and chemical data from (Bourgault and Rabenhorst, 2011).

**Source**

<http://www.sciencedirect.com/science/article/pii/S0016706111001972>

**References**

Rebecca R. Bourgault, Martin C. Rabenhorst. 2011. Genesis and characterization of manganiferous soils in the Eastern Piedmont, USA. *Geoderma*. 165:84-94.

**Examples**

```
# setup environment
library(aqp)
data(sp6)

# init SPC
depths(sp6) <- id ~ top + bottom
# convert non-standard Munsell colors
sp6$soil_color <- getClosestMunsellChip(sp6$color)

# profile sketches
par(mar=c(0,0,3,0))
plot(sp6, color='soil_color')
plot(sp6, color='Mn')
plot(sp6, color='Fe')
plot(sp6, color='pH')
plot(sp6, color='texture')
```

---

SPC.with.overlap

*Example SoilProfileCollection with Overlapping Horizons*

---

**Description**

A SoilProfileCollection with overlapping horizons, derived from a Dynamic Soil Properties project.

**Usage**

```
data(SPC.with.overlap)
```

**Format**

A SoilProfileCollection

---

```
spc2mpspline,SoilProfileCollection-method
      SoilProfileCollection wrapper for mpspline2::mpspline()
```

---

## Description

Generate mass-preserving splines for any numeric attribute in a `SoilProfileCollection` using `mpspline2::mpspline()`. `mpspline2` implements the method described in Bishop et al. (1999). Currently this function only works with a single `var_name` at a time.

## Usage

```
## S4 method for signature 'SoilProfileCollection'
spc2mpspline(
  object,
  var_name = NULL,
  method = c("est_1cm", "est_icm", "est_dcm"),
  pattern = "R|Cr|Cd|qm",
  hzdesgn = NULL,
  ...
)
```

## Arguments

<code>object</code>	A <code>SoilProfileCollection</code>
<code>var_name</code>	Column name in <code>@horizons</code> slot of <code>object</code> containing numeric values to spline
<code>method</code>	Options include "est_1cm" (default; 1cm estimates), "est_icm" (estimates over original layer boundaries), "est_dcm" (estimates over constant interval, specified with <code>d</code> argument to <code>mpspline3::mpspline()</code> ). Default value for <code>d</code> is <code>c(0, 5, 15, 30, 60, 100, 200)</code> .
<code>pattern</code>	Regex pattern to match for bottom of profile (passed to <code>minDepthOf()</code> ) default: "R Cr Cd qm"; only used if <code>hzdesgn</code> is specified
<code>hzdesgn</code>	Column name in <code>@horizons</code> slot of <code>object</code> containing horizon designations default: <code>NULL</code>
<code>...</code>	Additional arguments to <code>mpspline2::mpspline()</code>

## Details

This function now relies on the missing data checks provided by the `mpspline2` package. See `attr(..., 'removed')` to see whole profiles that were removed from the set. Horizons containing `NA` in the property of interest are dropped with a message.

Data completeness is assessed and the input `SoilProfileCollection` is filtered and truncated to create a container for the results from `mpspline2::mpspline()`.

**Value**

A SoilProfileCollection with 1cm slices. Spline variables are in columns prefixed with "spline\_" and RMSE/RMSE\_IQR are in columns prefixed with "rmse\_". If any profiles were removed from the collection, their profile IDs are stored in `attr(result, 'removed')`.

**Author(s)**

Andrew G. Brown

O'Brien, Lauren (2022). mpspline2: Mass-Preserving Spline Functions for Soil Data. R package version 0.1.6. <https://cran.r-project.org/package=mpspline2>

**Examples**

```
if (requireNamespace("mpspline2")) {
  data(sp1)
  depths(sp1) <- id ~ top + bottom

  res <- spc2mpspline(sp1, "prop")

  plotSPC(res[1:5,], color = "prop_spline", divide.hz = FALSE)
}
```

---

 spc\_in\_sync

*Quickly assess relative state of site and horizon slots*

---

**Description**

Determine "state" of SoilProfileCollection before or after major modifications of site or horizon slot contents.

Two logical checks are performed on the site and horizon tables, and a third element `valid` returns TRUE when both checks are TRUE.

Check 1: Same number of sites in site as number of sites in horizons. No intermingling of IDs, no orphan horizons, no sites without horizons (for now)

Check 2: Site IDs match coalesced profile ID from horizons. Ensures the same *relative* ordering, but horizons still may be out of order within profiles

**Usage**

```
spc_in_sync(object)
```

**Arguments**

object            A SoilProfileCollection

**Value**

data.frame

**Author(s)**

Andrew G. Brown

**Examples**

```
data(sp5)
spc_in_sync(sp5)
```

---

spec2Munsell

*Convert reflectance spectra to closest Munsell chip*

---

**Description**

Convert reflectance spectra to closest Munsell chip

**Usage**

```
spec2Munsell(
  x,
  res = 10,
  convert = TRUE,
  SO = c("CIE1931", "CIE1964"),
  illuminant = c("D65", "F2"),
  ...
)
```

**Arguments**

x                    reflectance spectra, must range from 380nm to 730nm with resolution specified in res

res                   spectra resolution in nm, typically 5nm or 10nm

convert              logical, convert sRGB coordinates to closest Munsell chip (see ?munsell)

SO                    CIE standard observer: these are the color matching functions defined by CIE and used to represent "average" human color perception. CIE1931 is the 2 degree standard observer more useful for describing color perception over very small areas or at distance. CIE1964 is the 10 degree standard observer, used for most industrial color matching applications.

illuminant      CIE standard illuminants:

- D65 represents average daylight
- F2 represents typical fluorescent lighting

...              further arguments to [col2Munsell\(\)](#)

### Details

See the [expanded tutorial](#) for additional examples.

### Value

output from [col2Munsell\(\)](#)

### Examples

```
# Munsell reference spectra
data("munsell.spectra.wide")

# convert to closest Munsell chip
# sRGB -> Munsell conversion via col2Munsell()
spec2Munsell(munsell.spectra.wide[, '10YR 3/3'])

# attempt several
cols <- c('10YR 6/2', '5YR 5/6', '10B 4/4', '5G 4/4', '2.5Y 8/2', '10YR 3/3', '7.5YR 2.5/2')

# most are exact or very close
z <- do.call(
  'rbind',
  lapply(cols, function(i) {
    spec2Munsell(munsell.spectra.wide[, i])
  })
)

# format Munsell notation from pieces
z$m <- sprintf("%s %s/%s", z$hue, z$value, z$chroma)

# compare
colorContrastPlot(
  m1 = cols,
  m2 = z$m,
  labels = c('original', 'spectral\ninterpretation')
```

```

)

## Not run:
if(requireNamespace("gower")) {
  # mix colors, return spectra, convert to color
  cols <- c('10YR 6/2', '5YR 5/6', '10B 4/4')
  res <- mixMunsell(cols, keepMixedSpec = TRUE, mixingMethod = 'reference')

  # note that they are slightly different
  res$mixed
  spec2Munsell(res$spec)
}

## End(Not run)

```

---

spectral.reference      *Standard Illuminants and Observers*

---

### Description

D65 and F2 standard illuminant spectral power distributions, CIE1931 Standard Observer (2 degree), and CIE1964 Supplemental Standard Observer (10 degree)

### Usage

```
data(spectral.reference)
```

### Format

An object of class `data.frame` with 71 rows and 9 columns.

  cex = 0.85
)

```

---

split,SoilProfileCollection-method

*Split a SoilProfileCollection object into a list of SoilProfileCollection objects.*

---

### Description

This function splits a SoilProfileCollection into a list of SoilProfileCollection objects using a site-level attribute to define groups or profile ID (idname(x)).

### Usage

```
## S4 method for signature 'SoilProfileCollection'
split(x, f, drop = TRUE, ...)
```

### Arguments

x	SoilProfileCollection object
f	character vector naming a single site-level attribute that defines groups, a ‘factor’ in the sense that as.factor(f) defines the grouping, or a list of such factors in which case their interaction is used for the grouping.
drop	logical indicating if levels that do not occur should be dropped (if f is a factor or a list). When drop=FALSE and f contains missing values an additional group "missing" is returned.
...	additional arguments are ignored

### Details

As of aqp 1.25, omission of f argument is no longer possible, as the base R generic is overloaded by this SoilProfileCollection method. This used to result in an "identity" split, according to idname(x), e.g. a list as long as length(x), with a single-profile SoilProfileCollection per list element. Replicate this behavior using f = idname(x) or f = profile\_id(x).

### Value

A list of SoilProfileCollection or NULL for empty result.

### Author(s)

D.E. Beaudette and A.G. Brown

### Examples

```
data(sp2)
depths(sp2) <- id ~ top + bottom

# add a more interesting site-level attribute
site(sp2) <- ~ surface
```

```

# using identity site-level attribute (profile ID)
p1 <- split(sp2, f = idname(sp2))
names(p1)
length(p1)

# using vector equal in length to number of profiles (profile ID, again)
p2 <- split(sp2, f = profile_id(sp2))
names(p2)
length(p2)

# which are both equivalent to setting `f` to NULL
p3 <- split(sp2, f = NULL)
names(p3)
length(p3)

# split on surface (age) site-level var
p4 <- split(sp2, f = "surface")
names(p4)
length(p4) # 5 unique "surfaces", 5 SPCs in result list

```

---

splitLogicErrors	<i>Split a SoilProfileCollection into a list based on types of horizon logic errors</i>
------------------	---

---

### Description

Uses checkHzDepthLogic to identify presence of depth logic errors, same depths, missing depths, and overlaps/gaps between the horizons of each profile in a SoilProfileCollection.

### Usage

```
splitLogicErrors(object, interact = FALSE, ...)
```

### Arguments

object	A SoilProfileCollection
interact	Calculate interaction between the four logic errors for groups? Default: FALSE always returns 4 groups, one for each logic error type.
...	Additional arguments to split.default, called when interact = TRUE

### Value

A named list of SoilProfileCollections (or NULL), with names: "depthLogic", "sameDepth", "missingDepth", "overlapOrGap". If interact = TRUE then the list elements groups determined by interaction() of the error types.

**Examples**

```

data(sp4)
depths(sp4) <- id ~ top + bottom

# no errors (all four list elements return NULL)
splitLogicErrors(sp4)

# NA in top depth triggers depth logic and missing depth errors
data(sp4)
sp4$top[1] <- NA
depths(sp4) <- id ~ top + bottom

splitLogicErrors(sp4)

# interact = TRUE gets errors for profile 1 in same group
# and allows you to pass extra arguments to split.default()
splitLogicErrors(sp4, interact = TRUE, sep = "_", drop = TRUE)

```

---

subApply

*Subset SPC based on result of performing function on each profile*

---

**Description**

subApply() is a function used for subsetting SoilProfileCollections. It currently does NOT support for "tidy" lexical features in the ... arguments passed to profileApply(). The expectation is that the function .fun takes a single-profile SoilProfileCollection and returns a logical value of length one. The use case would be for any logical comparisons that cannot be evaluated inline by subSPC() because they require more than simple logical operations.

**Usage**

```
subApply(object, .fun, ...)
```

**Arguments**

object	A SoilProfileCollection
.fun,	A function that takes a single profile, returns <i>logical</i> of length 1.
...	Additional arguments are passed to .fun

**Value**

A SoilProfileCollection.

**Author(s)**

Andrew G. Brown.

---

subset,SoilProfileCollection-method

*Subset a SoilProfileCollection with logical expressions*

---

### Description

subset() is a function used for extracting profiles from a SoilProfileCollection based on logical criteria. It allows the user to specify an arbitrary number of logical vectors (equal in length to site or horizon), separated by commas. The function includes some support for non-standard evaluation.

### Usage

```
## S4 method for signature 'SoilProfileCollection'  
subset(x, ..., greedy = FALSE)
```

### Arguments

x	A SoilProfileCollection
...	Comma-separated set of R expressions that evaluate as TRUE or FALSE. Length for individual expressions matches number of sites OR number of horizons, in object.
greedy	Use "greedy" matching for combination of site and horizon level matches? greedy = TRUE is the union, whereas greedy = FALSE (default) is the intersection (of site and horizon matches).

### Details

To minimize likelihood of issues with non-standard evaluation context, especially when using subset() inside another function, all expressions used in ... should be in terms of variables that are in the site or horizon data frame.

### Value

A SoilProfileCollection.

### Author(s)

Andrew G. Brown.

---

 subsetHz,SoilProfileCollection-method

*Subset the horizons in a SoilProfileCollection using logical criteria*

---

### Description

subsetHz() is a function used for extracting horizons from a SoilProfileCollection based on logical criteria.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
subsetHz(x, ..., drop = TRUE)
```

### Arguments

x	a SoilProfileCollection
...	Comma-separated set of R expressions that evaluate as TRUE or FALSE in context of horizon data frame. Length for individual expressions matches number of horizons, in x.
drop	Default: TRUE. When drop=FALSE placeholder horizons (profile ID with all other values NA) are created where the specified filter results in removal of all horizons.

### Details

To minimize likelihood of issues with non-standard evaluation context, especially when using subsetHz() inside another function, all expressions used in ... should be in terms of variables that are in the horizon data frame.

### Value

a SoilProfileCollection with a subset of horizons, possibly with some sites removed

### Examples

```
data(sp3)

depths(sp3) <- id ~ top + bottom

# show just horizons with 10YR hues
plot(subsetHz(sp3, hue == '10YR'))
```

---

subsetProfiles      *DEPRECATED use subset*

---

### Description

This function is used to subset SoilProfileCollection objects using either site-level or horizon-level attributes, or both.

### Usage

```
## S4 method for signature 'SoilProfileCollection'
subsetProfiles(object, s, h, ...)
```

### Arguments

object	object
s	fully-quoted search criteria for matching via site-level attributes
h	fully-quoted search criteria for matching via horizon-level attributes
...	not used

### Details

The `s` argument supplies a fully-quoted search criteria for matching via site or horizon-level attributes. The `h` argument supplies a fully-quoted search criteria for matching via horizon-level attributes. All horizons associated with a single horizon-level match (i.e. out of several, only a single horizon matches the search criteria) are returned. See examples for usage.

### Value

A SoilProfileCollection class object.

### Examples

```
# more interesting sample data
data(sp2)
depths(sp2) <- id ~ top + bottom
site(sp2) <- ~ surface

# subset by integer index, note that this does not re-order the profiles
plot(sp2[1:5, ])

# generate an integer index via pattern-matching
idx <- grep('modesto', sp2$surface, ignore.case=TRUE)
plot(sp2[idx, ])

# generate in index via profileApply:
# subset those profiles where: min(ph) < 5.6
```

```
idx <- which(profileApply(sp2, function(i) min(i$field_ph, na.rm=TRUE) < 5.6))
plot(sp2[idx, ])
```

---

summarizeSPC	<i>Perform summaries on groups (from group_by) and create new site or horizon level attributes</i>
--------------	--

---

### Description

summarize() is a function used for summarizing SoilProfileCollections. Specify the groups using the group\_by verb, and then (named) expressions to evaluate on each group. The result is a data.frame with one row per categorical level in the grouping variable and one column for each summary variable.

### Usage

```
summarizeSPC(object, ...)
```

### Arguments

object	A SoilProfileCollection
...	A set of (named) comma-delimited R expressions that resolve to a summary value. e.g groupmean = mean(c1ay, na.rm = TRUE)

### Value

A data.frame with one row per level in the grouping variable, and one column for each summary

### Author(s)

Andrew G. Brown

---

tauW	<i>Compute weighted naive and tau statistics for a cross-classification matrix</i>
------	--

---

### Description

tauW: Computes: (1) unweighted naive, (2) weighted naive, (3) unweighted tau, (4) weighted tau accuracy statistics

**Usage**

```
tauW(
  CM,
  W = diag(sqrt(length(as.matrix(CM)))),
  P = rep(1/nrow(as.matrix(CM)), nrow(as.matrix(CM)))
)

summaryTauW(result.tau)
```

**Arguments**

CM	a square confusion (cross-classification) matrix (rows: allocation, columns: reference)
W	weights: 1 on diagonals, [-1..1] off giving partial credit to this error
P	prior probability vector, length = number of rows/columns in CM and W
result.tau	tauW() result

**Details**

summaryTauW: prints a summary of the results from *tauW*

xtableTauW: formats a LaTeX table with results from *tauW* and saves it as a .tex file for import into a LaTeX document.

Input matrices CM and W may be in data.frame format and will be converted

Weights matrix W: 0 = no credit; 1 = full credit; -1 = maximum penalty

If absent, default is no partial credit, i.e., unweighted.

Prior probabilities vector P: If absent, P are equal priors for each class. Special value  $P = 0$  is interpreted as  $P = \text{column marginals}$ .

Error checks: CM must be square; P must have correct number of classes and sum to 1 +/- 0.0001; W & CM must be conformable

**Value**

Results are returned in a list with obvious R names

texcl_to_ssc	<i>Textural conversions</i>
--------------	-----------------------------

---

**Description**

These functions consist of several conversions between sand, silt and clay to texture class and visa versa, textural modifiers to rock fragments, and grain size composition to the family particle size class.

**Usage**

```
texcl_to_ssc(texcl = NULL, clay = NULL, sample = FALSE)
```

```
ssc_to_texcl(  
  sand = NULL,  
  clay = NULL,  
  simplify = FALSE,  
  as.is = FALSE,  
  droplevels = TRUE  
)
```

```
texmod_to_fragvoltot(texmod = NULL, lieutex = NULL)
```

```
texture_to_taxpartsize(  
  texcl = NULL,  
  clay = NULL,  
  sand = NULL,  
  fragvoltot = NULL  
)
```

```
texture_to_texmod(texture, duplicates = "combine")
```

```
fragvol_to_texmod(  
  object = NULL,  
  gravel = NULL,  
  cobbles = NULL,  
  stones = NULL,  
  boulders = NULL,  
  channers = NULL,  
  flagstones = NULL,  
  paragravel = NULL,  
  paracobbles = NULL,  
  parastones = NULL,  
  paraboulders = NULL,  
  parachanners = NULL,  
  paraflagstones = NULL,  
  as.is = TRUE,
```

```

    droplevels = TRUE
  )

```

### Arguments

texcl	vector of texture classes than conform to the USDA code conventions (e.g. c C, sillSIL, sllSL, cos COS)
clay	vector of clay percentages
sample	logical: should ssc be random sampled from the lookup table? (default: FALSE)
sand	vector of sand percentages
simplify	Passed to SoilTextureLevels() to set the number of possible texture classes. If TRUE, the ordered factor has a maximum of 12 levels, if FALSE (default) the ordered factor has a maximum of 21 levels (including e.g. very fine/fine/coarse variants)
as.is	logical: should character vectors be converted to factors? (default: TRUE)
droplevels	logical: indicating whether to drop unused levels in factors. This is useful when the results have a large number of unused classes, which can waste space in tables and figures.
texmod	vector of textural modifiers that conform to the USDA code conventions (e.g. gr GR, grv GRV)
lieutex	vector of in lieu of texture terms that conform to the USDA code conventions (e.g. gr GR, pg PG), only used when fragments or artifacts are > 90 percent by volume (default: NULL)
fragvoltot	vector of total rock fragment percentages
texture	vector of combinations of texcl, texmod, and lieutex (e.g. CL, GR-CL, CBV-S, GR)
duplicates	character: specifying how multiple values should be handled, options are "combined" (e.g. 'GR & GRV) or "max"(e.g. 'GRV')
object	data.frame: containing the following column names: gravel, cobbles, stones, boulders, channers, flagstones, paragravel, paracobbles, parastones, paraboulders, parachanners, paraflagstones
gravel	numeric: gravel volume %
cobbles	numeric: cobble volume %
stones	numeric: stone volume %
boulders	numeric: boulder volume %
channers	numeric: channer volume %
flagstones	numeric: flagstone volume %
paragravel	numeric: para gravel volume %
paracobbles	numeric: para cobble volume %
parastones	numeric: para stone volume %
paraboulders	numeric: para boulder volume %
parachanners	numeric: para channer volume %
paraflagstones	numeric: para flagstone volume %

## Details

These functions are intended to estimate missing values or allocate particle size fractions to classes. The `ssc_to_texcl()` function uses the same logic as the particle size estimator calculation in NASSIS to classify sand and clay into texture class. The results are stored in `soiltexture` and used by `texcl_to_ssc()` as a lookup table to convert texture class to sand, silt and clay. The function `texcl_to_ssc()` replicates the functionality described by Levi (2017). The `texmod_to_fragvol()` function similarly uses the logical from the `Exhibit618-11_texture_modifier.xls` spreadsheet to determine the textural modifier from the various combinations of rock and pararock fragments (e.g. GR and PGR).

When `sample = TRUE`, the results can be used to estimate within-class, marginal distributions of sand, silt, and clay fractions. It is recommended that at least 10 samples be drawn for reasonable estimates.

The function `texmod_to_fragvoldt` returns a `data.frame` with multiple `fragvoldt` columns differentiated by tailing abbreviations (e.g. `_r`) which refer to the following:

1. l = low
2. r = representative
3. h = high
4. nopf = no pararock fragments (i.e. total fragments - pararock fragments)

The function `texture_to_texmod()` parses texture (e.g. GR-CL) to extract the `texmod` values from it in the scenario where it is missing from `texmod` column. If multiple `texmod` values are present (for example in the case of stratified textures) and `duplicates = "combine"` they will be combined in the output (e.g. GR & CBV). Otherwise if `duplicates = "max"` the `texmod` with the highest rock fragment (e.g. CBV) will be returned.

Unlike the other functions, `texture_to_taxpartsize()` is intended to be computed on weighted averages within the family particle size control section. Also recall from the criteria that carbonate clay should be subtracted from clay content and added to silt content. Similarly, if the percent of very fine sand is known it should be subtracted from the sand, and added to the silt content. Unlike the other functions, `texture_to_taxpartsize()` is intended to be computed on weighted averages within the family particle size control section. Also recall from the criteria that carbonate clay should be subtracted from clay content and added to silt content. Similarly, if the percent of very fine sand is known it should be subtracted from the sand, and added to the silt content.

## Value

- `texcl_to_ssc`: A `data.frame` containing columns "sand", "silt", "clay"
- `ssc_to_texcl`: A character vector containing texture class
- `texmod_to_fragvoldt`: A `data.frame` containing columns "fragvoldt\_l", "fragvoldt\_r", "fragvoldt\_h", "fragvoldt\_l\_nopf", "fragvoldt\_r\_nopf", "fragvoldt\_h\_nopf"
- `texture_to_taxpartsize`: a character vector containing "taxpartsize" classes
- `texture_to_texmod`: a character vector containing "texmod" classes
- `texmod_to_fragvol`: a `data.frame` containing "texmod" and "lieutex" classes

# vector inputs
fragvol_to_texmod(gravel = 10, cobbles = 10)

```

**Description**

This function accepts soil texture components (sand, silt, and clay percentages) and plots a soil texture triangle with a "representative value" (point) and low-high region (polygon) defined by quantiles (estimated with `Hmisc::hdquantile`). Marginal quantiles of sand, silt, and clay are used to define the boundary of a low-high region. The default settings place the RV symbol at the texture defined by marginal medians of sand, silt, and clay. The default low-high region is defined by the 5th and 95th marginal percentiles of sand, silt, and clay.

**Usage**

```
textureTriangleSummary(
  ssc,
  p = c(0.05, 0.5, 0.95),
  delta = 1,
  rv.col = "red",
  range.border = "black",
  range.col = "RoyalBlue",
  range.alpha = 80,
  range.lty = 1,
  range.lwd = 2,
  main = "Soil Textures",
  legend.cex = 0.75,
  legend = TRUE,
  ...
)
```

**Arguments**

<code>ssc</code>	data.frame with columns: 'SAND', 'SILT', 'CLAY', values are percentages that should add to 100. No NA allowed.
<code>p</code>	vector of percentiles (length = 3) defining 'low', 'representative value', and 'high'
<code>delta</code>	grid size used to form low-high region
<code>rv.col</code>	color used for representative value (RV) symbol
<code>range.border</code>	color used for polygon border enclosing the low-high region
<code>range.col</code>	color used for polygon enclosing the low-high region
<code>range.alpha</code>	transparency of the low-high range polygon (0-255)
<code>range.lty</code>	line style for polygon enclosing the low-high region
<code>range.lwd</code>	line weight polygon enclosing the low-high region
<code>main</code>	plot title
<code>legend.cex</code>	scaling factor for legend
<code>legend</code>	logical, enable/disable automatic legend
<code>...</code>	further arguments passed to <code>soiltexture::TT.points</code>

**Value**

an invisible matrix with marginal percentiles of sand, silt, and clay

```

---

```
thompson.bell.darkness
```

*Thompson-Bell (1996) Index*

---

### Description

Calculate the "Profile Darkness Index" by the method of Thompson & Bell (1996) "Color index for identifying hydric conditions for seasonally saturated mollisols in Minnesota" DOI: 10.2136/sssaj1996.03615995006000060051x. The Thompson-Bell Index has been shown to reflect catenary relationships in some Mollisols of Minnesota (generally: wetter landscape positions = thicker, darker surfaces).

### Usage

```
thompson.bell.darkness(
  p,
  name = guessHzDesgnName(p, required = TRUE),
  pattern = "^A",
  value = "m_value",
  chroma = "m_chroma"
)
```

### Arguments

p	A single-profile SoilProfileCollection (e.g. via profileApply())
name	Column name containing horizon designations used to find A horizons (default: first column name containing 'name')
pattern	Regular expression to match A horizons (default: "^A" which means horizon designation <i>starts with</i> A)
value	Column name containing horizon color values (default: "m_value")
chroma	Column name containing horizon color chromas (default: "m_chroma")

### Value

A numeric vector reflecting horizon darkness (lower values = darker).

### Author(s)

Andrew G. Brown

---

traditionalColorNames *Traditional Soil Color Names*

---

**Description**

Traditional soil color names associated with select Munsell colors.

**Usage**

```
data(traditionalColorNames)
```

**Format**

An object of class `data.frame` with 482 rows and 2 columns.

**References**

Sourced from the "colorconverter" NASIS property script.

---

transform, SoilProfileCollection-method  
*Transform a SPC with expressions based on site or horizon level attributes*

---

**Description**

`transform()` is a function used for modifying columns in `SoilProfileCollections`.

It allows the user to specify an arbitrary number of expressions that resolve to the (re-)calculation of one or more site or horizon level attributes. For instance: `mutate(spc, thickness = hzdepb - hzdept)`. The expressions may depend on one another, and are evaluated from left to right.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
transform(`_data`, ...)
```

**Arguments**

<code>_data</code>	A <code>SoilProfileCollection</code>
<code>...</code>	Comma-separated set of R expressions e.g. <code>thickness = hzdepb - hzdept</code> , <code>hzdepm = hzdept + round(thk / 2)</code>

**Value**

A SoilProfileCollection

**Author(s)**

Andrew G. Brown.

---

unique,SoilProfileCollection-method

*Uniqueness within a SoilProfileCollection via MD5 Hash*

---

**Description**

Unique profiles within a SoilProfileCollection using and MD5 hash of select horizon and / or site level attributes.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
unique(x, vars, SPC = TRUE)
```

**Arguments**

x	a SoilProfileCollection
vars	Variables to consider in uniqueness.
SPC	logical return a SoilProfileCollection when TRUE, otherwise vector of profile indices

**Value**

SoilProfileCollection when SPC = TRUE, otherwise a vector of integers

**Examples**

```
# an example soil profile
x <- data.frame(
  id = 'A',
  name = c('A', 'E', 'Bhs', 'Bt1', 'Bt2', 'BC', 'C'),
  top = c(0, 10, 20, 30, 40, 50, 100),
  bottom = c(10, 20, 30, 40, 50, 100, 125),
  z = c(8, 5, 3, 7, 10, 2, 12)
)

# init SPC
depths(x) <- id ~ top + bottom

# horizon depth variability for simulation
```

```

horizons(x)$sd <- 2

# duplicate several times
x.dupes <- duplicate(x, times = 5)

# simulate some new profiles based on example
x.sim <- perturb(x, n = 5, thickness.attr = '.sd')

# graphical check
plotSPC(x.dupes, name.style = 'center-center')
plotSPC(x.sim, name.style = 'center-center')

# inspect unique results
plotSPC(unique(x.dupes, vars = c('top', 'bottom')), name.style = 'center-center')

# uniqueness is a function of variable selection
plotSPC(unique(x.sim, vars = c('top', 'bottom')), name.style = 'center-center')
plotSPC(unique(x.sim, vars = c('name')), name.style = 'center-center')

```

---

unroll

*Unroll Genetic Horizons*

---

## Description

Generate a discretized vector of genetic horizons along a user-defined pattern.

## Usage

```
unroll(top, bottom, prop, max_depth, bottom_padding_value = NA, strict = FALSE)
```

## Arguments

top	vector of upper horizon boundaries, must be an integer
bottom	vector of lower horizon boundaries, must be an integer
prop	vector of some property to be "unrolled" over a regular sequence
max_depth	maximum depth to which missing data is padded with NA
bottom_padding_value	value to use when padding missing data
strict	should horizons be strictly checked for self-consistency? defaults to FALSE

## Details

This function is used internally by several higher-level components of the aqp package. Basic error checking is performed to make sure that bottom and top horizon boundaries make sense. Note that the horizons should be sorted according to depth before using this function. The `max_depth` argument is used to specify the maximum depth of profiles within a collection, so that data from any profile shallower than this depth is padded with NA.

**Value**

a vector of "unrolled" property values

**Author(s)**

Dylan E. Beaudette

**References**

<http://casoilresource.lawr.ucdavis.edu/>

**Examples**

```
data(sp1)

# subset a single soil profile:
sp1.1 <- subset(sp1, subset=id == 'P001')

# demonstrate how this function works
x <- with(sp1.1, unroll(top, bottom, prop, max_depth=50))
plot(x, 1:length(x), ylim=c(90,0), type='b', cex=0.5)
```

---

us.state.soils

*US State Soils*

---

**Description**

A listing of the 50 US state soils, along with Puerto Rico and Virgin Islands.

**Usage**

```
data(us.state.soils)
```

**Format**

**state** state name

**abbreviated** abbreviated state name

**series** soil series name

---

validSpatialData,SoilProfileCollection-method  
*Check for valid spatial reference of profiles*

---

**Description**

Are coordinate column names defined in metadata and existing in the SoilProfileCollection?

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
validSpatialData(object)
```

**Arguments**

object            a SoilProfileCollection

**Value**

logical TRUE if column names are defined and correspond to existing data

---

warpHorizons            *Inflate / Deflate Horizon Thickness*

---

**Description**

This function applies a warping factor to the horizons of a single-profile SoilProfileCollection object. Warping values >1 will inflate horizon thickness, values <1 will deflate horizon thickness.

**Usage**

```
warpHorizons(x, fact, updateProfileID = TRUE, suffix = "-w")
```

**Arguments**

x                    a SoilProfileCollection object

fact                numeric or character; warping factor specified as a single numeric value, vector of numeric values (length = nrow(x)), or column name of a horizon level attribute containing numeric values

updateProfileID    logical; modify profile IDs

suffix              character; suffix added to profile IDs when updateProfileID = TRUE

**Value**

a modified version of x, SoilProfileCollection object

**Author(s)**

D.E. Beaudette and S.W. Salley

**Examples**

```

# create an example profile
s <- quickSPC('p1:AA|Bt1Bt1Bt1|Bt2Bt2B|Bt3|Cr|RRRRR')

# warp each horizon
# values > 1: inflation
# values < 1: deflation (erosion / compaction)
s.w <- warpHorizons(s, fact = c(1.3, 0.7, 0.8, 1, 1, 1))

# combine original + warped
x <- combine(s, s.w)

# compute profile bottom depths
.bottoms <- x[, , .LAST, .BOTTOM]

# change in total depth after warping
# used to vertically offset the warped profile
.yoff <- c(0, .bottoms[1] - .bottoms[2])

# depths for line segments connecting horizon tops
.y1 <- x[1, , .TOP]
.y2 <- x[2, , .TOP] + .yoff[2]

# sketches
# can't automatically add a depth axis
par(mar = c(0.5, 0, 0, 2))
plotSPC(
  x,
  name.style = 'center-center',
  cex.names = 0.8,
  width = 0.2,
  max.depth = 150,
  depth.axis = list(line = -3),
  y.offset = .yoff
)

# illustrate warping with arrows
arrows(x0 = 1 + 0.25, y0 = .y1, x1 = 2 - 0.25, y1 = .y2, len = 0.1, col = 2)

# manually add depth axis
axis(side = 4, line = -3.5, las = 1, at = seq(from = 0, to = 150, by = 25))

# apply to multiple profiles
# text-based template
.template <- c(
  'P1:AAA|BwBwBwBw|CCCCCCC|CdCdCdCd',

```

```

'P2:ApAp|AA|E|BhsBhs|Bw1Bw1|CCCCC',
'P3: A|Bt1Bt1Bt1|Bt2Bt2Bt2|Bt3|Cr|RRRRR'
)

# each horizon label is '10' depth-units (default)
s <- quickSPC(.template)

# random warping factor, by horizon
s$f <- runif(n = nrow(s), min = 0.8, max = 1.2)

# warp horizons by profile, result is a list of SPCs
s.w <- profileApply(s, FUN = warpHorizons, fact = 'f')

  max.depth = 165,
  depth.axis = list(line = -2)
)

```

---

wilson2022

*Example Data from Wilson et al. 2022*

---

### Description

An example SoilProfileCollection, derived from Wilson et al., 2022. Select data extracted from Appendix tables.

### Usage

```
data(wilson2022)
```

### Format

A SoilProfileCollection with the following elements. Total elemental analysis by lithium borate fusion.

Horizon level attributes:

- name: horizon designation
- Al2O3: total Al (wt %)
- Fe2O3: total Fe (wt %)
- K2O: total K (wt %)
- MgO: total Mg (wt %)
- Na2O: total Na (wt %)
- P2O5: total P (wt %)
- SiO2: total Si (wt %)
- CaO: total Ca(wt %)
- Alo: Oxalate Extractable Al (g/kg)
- Feo: Oxalate Extractable Fe (g/kg)
- Fed: Dithionite extractable Fe (g/kg)
- Fed\_minus\_Feo: Crystalline Fe (hydr)oxides (g/kg)
- CIA: Chemical Index of Alteration, see original paper (ratio, unitless)
- Fed\_div\_Fet: (ratio, unitless)
- Fet: Total Fe from lithium borate fusion (g/kg)
- resin\_Pi: Hedley phosphorus fractions (mg/kg)
- NaHCO3\_Pi: Hedley phosphorus fractions (mg/kg)
- labile\_Pi: Sum of resin Pi and NaHCO3 Pi (mg/kg)
- NaCO3\_Po: Hedley phosphorus fractions (mg/kg)
- NaOH\_Pi: Hedley phosphorus fractions (mg/kg)
- NaOH\_Po: Hedley phosphorus fractions (mg/kg)
- Ca\_Pi: Hedley phosphorus fractions (mg/kg)
- organic\_P: Sum of NaHCO3 and NaOH Po fractions (mg/kg)
- total\_P: Total P from lithium borate fusion (mg/kg)
- occluded\_P: Difference between total P and sum of Hedley P fractions (mg/kg)
- top: horizon top depth (cm)
- bottom: horizon bottom depth (cm)
- pedonID: pedon ID (serial number)

Site level attributes:

- pm: parent material group
- biome: biome

## References

**Examples**

```

data(wilson2022)

groupedProfilePlot(wilson2022, groups = 'pm',
  group.name.offset = -15, label = 'biome',
  name.style = 'center-center', color = 'CIA',
  cex.names = 0.66, cex.id = 0.66, width = 0.3,
  depth.axis = FALSE, hz.depths = TRUE)

groupedProfilePlot(wilson2022, groups = 'biome',
  group.name.offset = -15, label = 'pm',
  name.style = 'center-center', color = 'Fet',
  cex.names = 0.66, cex.id = 0.66, width = 0.3,
  depth.axis = FALSE, hz.depths = TRUE)

```

---

xtableTauW

*Format a LaTeX table with results*

---

**Description**

Format a LaTeX table with results

**Usage**

```
xtableTauW(result.tau, file.name = "tau_results_table.tex")
```

**Arguments**

result.tau	results returned by tauW
file.name	name of file to write output TeX file; Default: file.name="tau_results_table.tex"

---

[,SoilProfileCollection-method

*Matrix/data.frame-like access to profiles and horizons in a SoilProfileCollection*

---

**Description**

You can access the contents of a SoilProfileCollection by profile and horizon "index", i and j, respectively: spc[i, j, ...]. Subset operations are propagated to other slots (such as diagnostics or spatial) when they result in removal of sites from a collection.

- i refers to the profile position within the collection. By default the order is based on the C SORT order of the variable that you specified as your unique profile ID at time of object construction. Note that if your ID variable was numeric, then it has been sorted as a character.

- `j` refers to the horizon or "slice" index. This index is most useful when either a) working with `slice'd SoilProfileCollection` or b) working with single-profile collections. `j` returns the layer in the specified index positions for all profiles in a collection.
- `...` is an area to specify an expression that is evaluated in the subset. Currently supported
  - `.LAST` (last horizon in each profile): return the last horizon from each profile. This uses `i` but ignores the regular `j` index.
  - `.FIRST` (first horizon in each profile): return the last horizon from each profile. This uses `i` but ignores the regular `j` index.
  - `.HZID` (horizon index): return the horizon indices corresponding to `i+j+...` ("k") constraints
  - `.NHZ` (number of horizons): return the number of horizons in the profiles resulting from `i+j+...` ("k") constraints

### Usage

```
## S4 method for signature 'SoilProfileCollection'
x[i, j, ..., drop = TRUE]
```

### Arguments

<code>x</code>	a <code>SoilProfileCollection</code>
<code>i</code>	a numeric or logical value denoting profile indices to select in a subset
<code>j</code>	a numeric or logical value denoting horizon indices to select in a subset
<code>...</code>	non-standard expressions to evaluate in a subset
<code>drop</code>	Default: <code>TRUE</code> . When <code>drop=FALSE</code> placeholder horizons (profile ID with all other values <code>NA</code> ) are created where the specified <code>j</code> index results in removal of all horizons.

---

[[ *Get column of horizon or site data in a `SoilProfileCollection`*

---

### Description

Get the data from a column accessed by name. Column names other than profile ID are not shared between site and horizons. Bonus: `[[` gives access to all site and horizon level variables in tab complete for RStudio using the `magrittr` pipe operator!

### Usage

```
## S4 method for signature 'SoilProfileCollection,ANY,ANY'
x[[i, j]]
```

### Arguments

<code>x</code>	a <code>SoilProfileCollection</code>
<code>i</code>	an expression resolving to a single column name in site or horizon table
<code>j</code>	(not used)

**Examples**

```

data(sp2)
depths(sp2) <- id ~ top + bottom
site(sp2) <- ~ surface

# get with [[
sp2[['surface']]

# get using "unknown" expression:
# "2nd + 3rd horizon column names"
for(i in horizonNames(sp2)[2:3])
  print(sp2[[i]])

data(sp5)

# some column names to work with
rgb.columns <- c("R25", "G25", "B25")

res <- lapply(rgb.columns, function(x) {

  # [[ allows you to access column names in a loop
  round(sp5[[x]] * 255)

})

# rename scaled results
names(res) <- paste0(rgb.columns, "_scl")

# add horizon ID to results
result <- data.frame(hzID = hzID(sp5), do.call('cbind', res))
head(result)

# join result back into horizons
horizons(sp5) <- result

```

---

[[<- *Add or change column of horizon or site data in a SoilProfileCollection*

---

**Description**

Add or change the data from a column accessed by name. Column names other than profile ID are not shared between site and horizons. The benefit of using double bracket setter over \$ is that name can be calculated, whereas with \$, it must be known a priori and hard coded.

When using the double bracket setter the length of input and output matching either the number of sites or number of horizons is used to determine which slot new columns are assigned to.

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection,ANY,ANY'
x[[i]] <- value
```

**Arguments**

x	a SoilProfileCollection
i	an expression resolving to a single column name in site or horizon table-
value	New value to replace – unit length or equal in length to number of sites or horizons in the collection.

---

\$ *Get data from column of horizon or site data in a SoilProfileCollection*

---

**Description**

Get the data from a column accessed by name `x$name`. Column names other than profile ID are not shared between site and horizons.

**Usage**

```
## S4 method for signature 'SoilProfileCollection'
x$name
```

**Arguments**

x	a SoilProfileCollection
name	a single column name in site or horizon table

**Examples**

```
data(sp1)

depths(sp1) <- id ~ top + bottom

# get data from a column by name (prop)
sp1$prop
```

---

`$<-` *Set data in column of horizon or site data in a SoilProfileCollection*

---

**Description**

Set the data in a column accessed by name `spc$name`. Column names other than profile ID are not shared between site and horizons.

When using `$<-`, the length of input and output matching either the number of sites or number of horizons is used to determine which slot new columns are assigned to. Use `site(x)$name <- value` or `horizons(x)$name <- value` to be explicit about which slot is being accessed.

**Usage**

```
## S4 replacement method for signature 'SoilProfileCollection'  
x$name <- value
```

**Arguments**

<code>x</code>	a SoilProfileCollection
<code>name</code>	a single column name in site or horizon table
<code>value</code>	Replacement values: unit length or equal to number of horizons or sites.
