

# Package ‘geohabnet’

April 8, 2024

**Title** Geographical Risk Analysis Based on Habitat Connectivity

**Version** 2.1.2

**Date** 2024-04-05

## Description

The geohabnet package is designed to perform a geographically or spatially explicit risk analysis of habitat connectivity. Xing et al (2021) <[doi:10.1093/biosci/biaa067](https://doi.org/10.1093/biosci/biaa067)> proposed the concept of cropland connectivity as a risk factor for plant pathogen or pest invasions. As the functions in geohabnet were initially developed thinking on cropland connectivity, users are recommended to first be familiar with the concept by looking at the Xing et al paper. In a nutshell, a habitat connectivity analysis combines information from maps of host density, estimates the relative likelihood of pathogen movement between habitat locations in the area of interest, and applies network analysis to calculate the connectivity of habitat locations.

The functions of geohabnet are built to conduct a habitat connectivity analysis relying on geographic parameters (spatial resolution and spatial extent), dispersal parameters (in two commonly used dispersal kernels: inverse power law and negative exponential models), and network parameters (link weight thresholds and network metrics).

The functionality and main extensions provided by the functions in geohabnet to habitat connectivity analysis are

- a) Capability to easily calculate the connectivity of locations in a landscape using a single function, such as `sensitivity_analysis()` or `msean()`.
- b) As backbone datasets, the geohabnet package supports the use of two publicly available global datasets to calculate cropland density. The backbone datasets in the geohabnet package include crop distribution maps from Monfreda, C., N. Ramankutty, and J. A. Foley (2008) <[doi:10.1029/2007gb002947](https://doi.org/10.1029/2007gb002947)> ``Farming the planet: 2. Geographic distribution of crop areas, yields, physiological types, and net primary production in the year 2000, Global Biogeochem. Cycles, 22, GB1022" and International Food Policy Research Institute (2019) <[doi:10.7910/DVN/PRFF8V](https://doi.org/10.7910/DVN/PRFF8V)> ``Global Spatially-Disaggregated Crop Production Statistics Data for 2010 Version 2.0, Harvard Data-verse, V4". Users can also provide any other geographic dataset that represents host density.
- c) Because the geohabnet package allows R users to provide maps of host density (as originally in Xing et al (2021)), host landscape density (representing the geographic distribution of either crops or wild species), or habitat distribution (such as host landscape density adjusted by climate suitability) as inputs, we propose the term habitat connectivity.
- d) The geohabnet package allows R users to customize parameter values in the habitat connectivity analysis, facilitating context-specific (pathogen- or pest-specific) analyses.

e) The geohabnet package allows users to automatically visualize maps of the habitat connectivity of locations resulting from a sensitivity analysis across all customized parameter combinations. The primary function is sean() and sensitivity analysis().

Most functions in geohabnet provide as three main outcomes: i) A map of mean habitat connectivity across parameters selected by the user, ii) a map of variance of habitat connectivity across the selected parameters, and iii) a map of the difference between the ranks of habitat connectivity and habitat density.

Each function can be used to generate these maps as 'final' outcomes.

Each function can also provide intermediate outcomes, such as the adjacency matrices built to perform the analysis, which can be used in other network analysis.

Refer to article at <<https://garrettlab.github.io/HabitatConnectivity/articles/analysis.html>> to see examples of each function and how to access each of these outcome types.

To change parameter values, the file called parameters.yaml stores the parameters and their values, can be accessed using get\_parameters() and set new parameter values with set\_parameters().

Users can modify up to ten parameters.

`.indices`

*Internal function to extract risk indices from a list of crop rasters.*

## Description

Internal function to extract risk indices from a list of crop rasters.

## Usage

```
.indices(crop_rasters)
```

## Arguments

`crop_rasters` List of raster objects.

## Value

A list of risk indices.

`connectivity`

*Calculate and plot maps*

## Description

Calculate mean, variance and difference. The result is produced in form of maps plotted with predefined settings. Currently, the settings for plot cannot be customized. Default value is TRUE for all logical arguments

## Usage

```
connectivity(  
  host,  
  indices,  
  global = FALSE,  
  east = NULL,  
  west = NULL,  
  geoscale = NULL,  
  res = reso(),  
  pmean = TRUE,  
  pvar = TRUE,  
  pdiff = TRUE,  
  outdir = tempdir()  
)
```

## Arguments

host	SpatRaster. Host density map aka SpatRaster object
indices	SpatRaster. Collection of risk indices.
global	Logical. TRUE if global analysis is desired, FALSE otherwise. east and west are required when TRUE.
east	SpatRaster. Collection of risk indices on eastern extent.
west	SpatRaster. Collection of risk indices on western extent. When TRUE, geoscale is ignored. Default is TRUE.
geoscale	Vector. geographical scale. Default is NULL.
res	Numeric. Map resolution. This value is used in aggregation and dis-aggregation operation. Default is <a href="#">reso()</a> .
pmean	Logical. TRUE if map of mean should be plotted, FALSE otherwise.
pvar	Logical. TRUE if variance map should be plotted, FALSE otherwise.
pdiff	Logical. TRUE if difference map should be plotted, FALSE otherwise.
outdir	Character. Output directory for saving raster in TIFF format. Default is <a href="#">tempdir()</a> .

## Details

indexes are actually risk indices i.e. lis of spatRaster objects resulting from operations on crop's raster and parameters provided in either `parameters.yaml` or [sean\(\)](#).

It will save all the opted plots using - pmean, pvar and pdiff. File will be saved in provided value of outdir or [tempdir\(\)](#). If [interactive\(\)](#) is TRUE, then plots can be seen in active plot window. E.g. Rstudio. The maps are plotted using SpatRaster object. These objects are available as a return value of this function.

## Value

Gmap. See details.

`cropharvest_rast`      *Get raster object for crop*

### Description

Get cropland information in a form of raster object from data source for crop

### Usage

```
cropharvest_rast(crop_name, data_source)
```

### Arguments

<code>crop_name</code>	Name of the crop
<code>data_source</code>	Data source for cropland information

### Value

Raster.

### Examples

```
cropharvest_rast("avocado", "monfreda")
```

`crops_rast`      *Get sum of rasters for individual crops*

### Description

Takes crop names and returns raster object which is sum of raster of individual crops. Currently, only supports crops listed in [geodata::monfredaCrops\(\)](#), [geodata::spamCrops\(\)](#). If crop is present in multiple sources, then their mean is calculated.

### Usage

```
crops_rast(crop_names)
```

### Arguments

<code>crop_names</code>	A named list of source along with crop names
-------------------------	--

### Value

SpatRaster. Raster object which is sum of all the individual crop raster

**See Also**[cropharvest\\_rast\(\)](#)**Examples**

```
crops_rast(list(monfreda = c("wheat", "barley"), mapspam2010 = c("wheat", "potato")))
```

---

**dist\_methods***Distance methods supported*

---

**Description**

Contains supported strategies to calculate distance between two points. Use of one the methods in [sean\(\)](#) or [sensitivity\\_analysis\(\)](#).

**Usage**

```
dist_methods()
```

**Value**

vector

**Examples**

```
dist_methods()
```

---

**GeoModel-class***GeoModel class*

---

**Description**

A ref class to represent results of dispersal models.

**Fields**

**matrix** An adjacency matrix to represent network.

---

GeoNetwork-class	<i>GeoNetwork</i>
------------------	-------------------

---

## Description

An S4 class representing a network of geographical data. This will wrap all the results from the risk analysis using `sean()` or `sensitivity_analysis()`. This class contains the field from Gmap class which has results in the form of SpatRaster and TIFF file.

## Usage

```
## S4 replacement method for signature 'GeoNetwork'  
host_density(x) <- value
```

## Arguments

x	GeoNetwork.
value	SpatRaster.

## Value

GeoNetwork.

## Slots

`rasters` A list of GeoRasters objects.  
`host_density` A SpatRaster representing the host density.  
`me_rast` A raster representing mean risk index.  
`me_out` Character. A file path to the mean risk index raster.  
`diff_rast` A raster representing difference.  
`diff_out` Character. A file path to the difference raster.  
`var_rast` A raster representing variance.  
`var_out` Character. A file path to the variance raster.

---

GeoRasters-class      *GeoRaster class*

---

## Description

A class to represent raster vis-a-vis risk indices. This class encapsulates the results of apply dispersal models and metrics.

## Fields

`host_density` SpatRaster. A spatial raster representing host density.

`rasters` List. List of raster representing risk indices. These are of type GeoModels.

`global` Boolean. True if contains GlobalRast object, False otherwise.

---

`geoscale_param`      *Get geographical scales from the parameters*

---

## Description

This function returns a list of geographical scales set in global and custom extent in `parameters.yaml`. If `global` is TRUE, the `CustomExt` is ignored.

## Usage

```
geoscale_param(gparams = load_parameters())
```

## Arguments

`gparams`      Optional. `load_parameters()` or null

## Value

Vector. A set of geographical scales

**get\_parameters***Get Parameters***Description**

Retrieves the parameters and copies the parameter file to the specified output path.

**Usage**

```
get_parameters(out_path = tempdir(), iwindow = FALSE)
```

**Arguments**

- |          |  |
|----------|--|
| out_path | character. The output path where the parameter file will be copied. Default is temporary directory <a href="#">tempdir()</a> |
| iwindow  | logical. If TRUE, prompts the user to select the output directory using a file chooser window. Default is FALSE              |

**Details**

Using configuration file is an alternative to [sean\(\)](#)

**Value**

character. The path to the copied parameter file.

**See Also**

[set\\_parameters\(\)](#)

**Examples**

```
get_parameters()
get_parameters(out = tempdir())
```

**get\_rasters***Get rasters object from parameters***Description**

Takes named list of hosts as an input. See host object in [get\\_parameters\(\)](#) or [load\\_parameters\(\)](#). This is also a wrapper of [crops\\_rast\(\)](#). Function creates 2 raster object - one is a sum of all the crops specified under sources and other using the provided raster file. See [tiff\\_toRaster\(\)](#)

**Usage**

```
get_rasters(hosts)
```

**Arguments**

hosts      List of hosts and values. It is synonym to Hosts object in parameters

**Value**

List of SpatRaster.

**See Also**

[load\\_parameters\(\)](#), [get\\_parameters\(\)](#), [tiff\\_toRaster\(\)](#), [cropHarvest\\_rast\(\)](#)

**Examples**

```
# Get default rasters
## Not run:
get_rasters(list(mapspam2010 = c("wheat"), monfreda = c("avocado"), file = "some_raster.tif"))

## End(Not run)
```

**Description**

A class to represent raster for global scales. Global scales are accessible using [global\\_scales\(\)](#). However, this class encapsulates the results of apply dispersal models and metrics.

**Fields**

**east** A list of raster for eastern hemisphere.

**west** A list of raster for western hemisphere.

global_scales	<i>Global geographical extent</i>
---------------	-----------------------------------

### Description

See geographical extents used in global analysis. Returns eastern and western hemisphere extents. Each extent is in the form of c(Xmin, Xmax, Ymin, Ymax).

### Usage

```
global_scales()
```

### Details

Separate analysis on geographical scales of eastern and western hemisphere are combined to run global analysis.

### Value

List. Named list with scales for eastern and western hemisphere

### See Also

[set\\_global\\_scales\(\)](#)

Gmap-class	<i>Gmap class</i>
------------	-------------------

### Description

An S4 class to represent various maps in the form of SpatRaster.

### Usage

```
setmaps(x, me, vari, dif)
```

### Arguments

- x Gmap object.
- me SpatRaster. A raster representing mean risk index.
- vari SpatRaster. A raster representing variance.
- dif SpatRaster. A raster representing difference.

### Value

Gmap object.

**Slots**

`me_rast` A raster representing mean risk index.  
`me_out` Character. A file path to the mean risk index raster.  
`diff_rast` A raster representing difference.  
`diff_out` Character. A file path to the difference raster.  
`var_rast` A raster representing variance.  
`var_out` Character. A file path to the variance raster.

---

**gplot**

*Plot a Raster\* object*

---

**Description**

This is a wrapper for `terra::plot()`

**Usage**

```
gplot(x, ...)
```

**Arguments**

<code>x</code>	a Raster* object
<code>...</code>	additional arguments passed to <code>terra::plot()</code>

**Value**

a plot

**Examples**

```
r <- terra::rast(nrows=108, ncols=21, xmin=0, xmax=10)
gplot(r)
gplot(r, col = "red")
gplot(r, col = "red", breaks = 10)
```

---

<b>hci_diff</b>	<i>Calculate difference map</i>
-----------------	---------------------------------

---

## Description

This function produces a map of difference b/w mean and sum indexes in rank of cropland harvested area fraction.

## Usage

```
hci_diff(x, y, global, geoscale, res = reso(), outdir = tempdir())
```

## Arguments

x	SpatRaster.
y	SpatRaster.
global	Logical. TRUE if global analysis is desired, FALSE otherwise. east and west are required when TRUE.
geoscale	Numeric vector. x will be cropped to this extent.
res	Numeric. Map resolution. This value is used in aggregation and dis-aggregation operation. Default is <code>reso()</code> .
outdir	Character. Output directory for saving raster in TIFF format. Default is <code>tempdir()</code> .

## Details

Ideally, the function is tested to yield desired results when `length(which(y[] > 0)) > length(which(x[] > 0))`.

## Value

RiskMap. Contains result in the form of SpatRaster objects and file path of the saved maps.

---

<b>hci_mean</b>	<i>Calculate mean of raster objects</i>
-----------------	---

---

## Description

Wrapper for `terra::mean()`. Calculates mean of list of rasters.

**Usage**

```
hci_mean(
  indices,
  global = FALSE,
  east = NULL,
  west = NULL,
  geoscale = NULL,
  res = reso(),
  plt = TRUE,
  outdir = tempdir()
)
```

**Arguments**

indices	List of SpatRasters. This input represents the spatial raster collection for which mean is to be calculated.
global	Logical. TRUE if global analysis is desired, FALSE otherwise. east and west are required when TRUE.
east	SpatRaster. Collection of risk indices on eastern extent.
west	SpatRaster. Collection of risk indices on western extent. When TRUE, geoscale is ignored. Default is TRUE.
geoscale	Vector. geographical scale. Default is NULL.
res	Numeric. Map resolution. This value is used in aggregation and dis-aggregation operation. Default is <a href="#">reso()</a> .
plt	TRUE if need to plot mean map, FALSE otherwise.
outdir	Character. Output directory for saving raster in TIFF format. Default is <a href="#">tempdir()</a> .

**Value**

RiskMap. Contains result in the form of SpatRaster objects and file path of the saved maps.

---

hci\_variance

*Calculate variance of CCRI*

---

**Description**

This function produces a map of variance of CCRI based on input parameters

**Usage**

```
hci_variance(
  indices,
  rast,
  global,
  east = NULL,
```

```

    west = NULL,
    geoscale,
    res = reso(),
    outdir = tempdir()
)

```

### Arguments

<code>indices</code>	SpatRaster. Collection of risk indices.
<code>rast</code>	SpatRaster. Template for variance output
<code>global</code>	Logical. TRUE if global analysis is desired, FALSE otherwise. <code>east</code> and <code>west</code> are required when TRUE.
<code>east</code>	SpatRaster. Collection of risk indices on eastern extent.
<code>west</code>	SpatRaster. Collection of risk indices on western extent. When TRUE, <code>geoscale</code> is ignored. Default is TRUE.
<code>geoscale</code>	Vector. geographical scale. Default is NULL.
<code>res</code>	Numeric. Map resolution. This value is used in aggregation and dis-aggregation operation. Default is <code>reso()</code> .
<code>outdir</code>	Character. Output directory for saving raster in TIFF format. Default is <code>tempdir()</code> .

### Value

RiskMap. Contains result in the form of SpatRaster objects and file path of the saved maps.

`host_density<-`      *Set the host density.*

### Description

Sets the host density slot in the GeoNetwork object

### Usage

```
host_density(x) <- value
```

### Arguments

<code>x</code>	the GeoNetwork object.
<code>value</code>	SpatRaster.

---

**inv\_powerlaw***Dispersal kernels*

---

**Description**

-[`inv_powerlaw()`] Get parameters and values pertaining to the inverse power law model.  
 -  
 [`neg_expo()`] Get parameters and values pertaining to the negative exponential model.

**Usage**

```
inv_powerlaw(
  params = load_parameters(),
  betas = NULL,
  mets = NULL,
  we = NULL,
  linkcutoff = NULL
)

neg_expo(
  params = load_parameters(),
  gammas = NULL,
  mets = NULL,
  we = NULL,
  linkcutoff = NULL
)
```

**Arguments**

<code>params</code>	Object. <a href="#">load_parameters()</a> by default. If not provided, the function will require all other parameters. It takes the precedence over other parameters.
<code>betas</code>	Numeric. Parameter for calculating the inverse power law.
<code>mets</code>	Character. Each of these metrics is applied to the adjacency matrix produced in the intermediate step.
<code>we</code>	Numeric The link weights to be used in the network analysis.
<code>linkcutoff</code>	Numeric. Currently used as a parameter to calculate centrality in the network.
<code>gammas</code>	Numeric. Parameter for calculating the negative exponential.

**Details**

The list object has following values used in running analysis  
 -`beta` Parameter for calculating the inverse power law.  
 -`gamma` Parameter for calculating the negative exponential.  
 -`metrics` Each of these metrics is applied to the adjacency matrix produced in the intermediate step.  
 -`weights` The link weights to be used in the network analysis.  
 -`cutoff` Currently used as a parameter to calculate centrality in the network - `betweenness\(\)` and `closeness\(\)`. As defined in `igraph::betweenness\(\)`, it's the maximum length to consider when calculating centrality. If zero or negative, then there is no such limit.

**Value**

List with parameters and values. See details.

---

load\_parameters

*Load Parameters from YAML File*

---

**Description**

This function loads parameters from a YAML file and stores them in an object.

**Usage**

```
load_parameters(filepath = .param_fp())
```

**Arguments**

filepath Path to the YAML file containing the parameters. By default, it takes the value of `parameters.yaml` in R user’s directory.

**Value**

object with parameters and values

**Examples**

```
# Load parameters from default file
load_parameters()
```

---

`mapspam`*Supported sources for Mapspam*

---

**Description**

Supported sources for Mapspam

**Usage**`mapspam()`

`monfreda`*Supported sources for monfreda*

---

**Description**

Supported sources for monfreda

**Usage**`monfreda()`

---

`nn_sum`*Calculation on network metrics a.k.a centralities.*

---

**Description**

These are functions under the [igraph](#) package adapted to calculate habitat connectivity. In the context of habitat connectivity, the functions can be interpreted as follows:

- [nn\_sum()]: Calculates the sum of nearest neighbors [igraph::graph.knn\(\)](#).
- [node\_strength()]: Calculates the sum of edge weights of adjacent nodes [igraph::graph.strength\(\)](#).
- [betweenness()]: Calculates the node betweenness based on the number of shortest paths. Because the [igraph::betweenness\(\)](#) function in [igraph](#) interprets link weights as distances to calculate the shortest paths, the [betweenness\(\)](#) function in [geohabnet](#) transforms the link weights (or the relative likelihood of pathogen or pest movement) in the adjacency matrix so that higher link weight values will be the shortest (or more likely) paths for pathogen or pest movement.
- [ev()]: Calculates the eigenvector centrality of positions within the network [igraph::evcent\(\)](#).
- [closeness()]: measures how many steps is required to access every other vertex from a given vertex [igraph::closeness\(\)](#). Because the [igraph::closeness\(\)](#) function in [igraph](#) interprets link weights as distances to calculate the shortest paths, the [closeness\(\)](#) function in [geohabnet](#) transforms the link weights (or the relative likelihood of pathogen or pest movement) in the adjacency matrix so that higher link weight values will be the shortest (or more likely) paths for pathogen or pest movement.
- [degree()]: number of adjacent edges [igraph::degree\(\)](#).
- [pagerank()]: page rank score for vertices [igraph::page\\_rank\(\)](#).

**Usage**

```
nn_sum(crop_dm, ...)

node_strength(crop_dm, ...)

betweenness(crop_dm, ...)

ev(crop_dm, ...)

degree(crop_dm, ...)

closeness(crop_dm, ...)

pagerank(crop_dm, ...)
```

**Arguments**

crop_dm	A square adjacency matrix, in which rows and columns names represent nodes (or locations) and each entry indicate the relative likelihood of pathogen or pest movement between a pair of nodes. In the internal workflow, the adjacency matrix comes as a result of operations within <a href="#">sean()</a> function. This weight represents the importance of the network metric in the habitat connectivity analysis.
...	arguments to corresponding igraph fun

**Value**

SpatRaster. Representing connectivity of each node or location.

**See Also**

Other metrics: [supported\\_metrics\(\)](#)

**reset\_params**

*Reset parameters.yaml*

**Description**

Resets the values in the `parameters.yaml` file to the default initial values.

**Usage**

```
reset_params()
```

**Value**

Logical. TRUE if function was successfully executed

## Examples

```
reset_params()
```

---

reso

*Get resolution value*

---

## Description

Resolution stored in parameter `.yaml`. If not present it will result default value.

## Usage

```
reso()
```

## Value

Numeric. Resolution from `parameters.yaml`. Default is 24.

---

RiskMap-class

*RiskMap class*

---

## Description

An S4 class representing resulting maps from the specific operation type.

## Fields

map Character. A file path to the map.

rpid SpatRaster. This is one of the risk maps.

spr SpatRaster. A spatial raster representing the risk index.

fp Character. A file path to the risk index raster.

---

**risk\_indices***Get risk indices*

---

**Description**

Get risk indices from GeoRasters object.

**Usage**

```
risk_indices(ri)
```

**Arguments**

ri	GeoRasters object
----	-------------------

**Details**

This function will unpack SpatRasters from GeoMadel and thus is [future::future\(\)](#) safe.

**Value**

List of risk indices. If the `ri` is global, the list will contain two elements, one for each hemisphere. e.g. `list(east = list(), west = list())`. If the `ri` is not global, the list will contain a single element, e.g. `list()`.

---

**sa\_onrasters***Run sensitivity analysis*

---

**Description**

Same as [sensitivity\\_analysis\(\)](#) but it takes raster object and other parameters as an input.

- `sa_onrasters()` is a wrapper around `sean()` function. Takes raster object and other parameters as an input.
- `msean_onrast()` same as `sa_onrasters()`. Use this for side effects + results. Produces and plots the maps for the outcomes and results are returned as an object. It produces and plots the maps for the outcomes and results are returned as an object.

## Usage

```
sa_onrasters(rast, link_thresholds = c(0), hd_thresholds = c(0), ...)

msean_onrast(
  global = TRUE,
  geoscale = NULL,
  res = reso(),
  outdir = tempdir(),
  ...
)
```

## Arguments

rast	Raster object which will be used in analysis.
link_thresholds	Numeric vector. link threshold values
hd_thresholds	Numeric vector. host density threshold values
...	Additional parameters to be passed to <a href="#">sean()</a> .
global	Logical. TRUE if global analysis, FALSE otherwise. Default is TRUE
geoscale	Numeric vector. Geographical coordinates in the form of c(Xmin, Xmax, Ymin, Ymax) which EPSG:4326 in coordinate reference system. If geoscale is NULL, the extent is extracted from rast(SpatRaster) using <a href="#">terra::ext()</a> .
res	Numeric. Resolution of the raster. Default is <a href="#">reso()</a> .
outdir	Character. Output directory for saving raster in TIFF format. Default is <a href="#">tempdir()</a> .

## Details

Error not handled for non-overlapping extents.

## Value

A list of calculated CCRI indices after operations. An index is generated for each combination of paramters. One combination is equivalent to [sean\(\)](#) function.

res3 <- msean_onrast(rast = rr[[1]],
                      link_thresholds = c(0.000001),
                      hd_thresholds = c(0.00015))
```

sean

*Sensitivity analysis across maps of habitat connectivity*

## Description

This function performs a sensitivity analysis across different values of habitat connectivity for each location in a map. For each combination of selected parameters, an index of habitat connectivity is calculated. [sensitivity\\_analysis\(\)](#) is a wrapper around [sean\(\)](#) function.

- `msean()` is a wrapper around `sean()` function. It has additional argument to specify maps which are calculated using `connectivity()` function. The maps are essentially the risk network.

## Usage

```
sean(
  rast,
  global = TRUE,
  geoscale = NULL,
  agg_methods = c("sum", "mean"),
  dist_method = "geodesic",
  link_threshold = 0,
```

```

hd_threshold = 0,
res = reso(),
inv_pl = inv_powerlaw(NULL, betas = c(0.5, 1, 1.5), mets = c("betweeness",
  "NODE_STRENGTH", "Sum_of_nearest_neighbors", "eigenVector_centrAlitY"), we = c(50,
  15, 15, 20), linkcutoff = -1),
neg_exp = neg_expo(NULL, gammas = c(0.05, 1, 0.2, 0.3), mets = c("betweeness",
  "NODE_STRENGTH", "Sum_of_nearest_neighbors", "eigenVector_centrAlitY"), we = c(50,
  15, 15, 20), linkcutoff = -1)
)

msean(
  rast,
  global = TRUE,
  geoscale = NULL,
  res = reso(),
  ...,
  outdir = tempdir()
)

```

## Arguments

rast	Raster object which will be used in analysis.
global	Logical. TRUE if global analysis, FALSE otherwise. Default is TRUE
geoscale	Numeric vector. Geographical coordinates in the form of c(Xmin, Xmax, Ymin, Ymax) which EPSG:4326 in coordinate reference system. If geoscale is NULL, the extent is extracted from rast(SpatRaster) using <a href="#">terra::ext()</a> .
agg_methods	Character. One or both the values - SUM, MEAN. Aggregation strategy for scaling the input raster to the desired resolution.
dist_method	Character. The method to calculate the distance matrix.
link_threshold	Numeric. A threshold value for link weight. All link weights that are below this threshold will be replaced with zero for the connectivity analysis. Link weights represent the relative likelihood of pathogen, pest, or invasive species movement between a pair of host locations, which is calculated using gravity models based on host density (or availability) and dispersal kernels.
hd_threshold	Numeric. A threshold value for host density. All locations with a host density below the selected threshold will be excluded from the connectivity analysis, which focuses the analysis on the most important locations. The values for the host density threshold can range between 0 and 1; if value is 1, all locations will be excluded from the analysis and 0 will include all locations in the analysis. Selecting a threshold for host density requires at least knowing what is the maximum value in the host density map to avoid excluding all locations in the analysis. if value is 1, all locations will be excluded from the analysis and 0 will include all locations in the analysis. Selecting a threshold for host density requires at least knowing what is the maximum value in the host density map to avoid excluding all locations in the analysis.
res	Numeric. Resolution of the raster. Default is <a href="#">reso()</a> .

inv_pl	List. A named list of parameters for inverse power law. See details.
neg_exp	List. A named list of parameters for inverse negative exponential. See details. All locations with a host density below the selected threshold will be excluded from the connectivity analysis, which focuses the analysis on the most important locations. The values for the host density threshold can range between 0 and 1;
...	arguments passed to <a href="#">sean()</a>
outdir	Character. Output directory for saving raster in TIFF format. Default is <a href="#">tempdir()</a> .

## Details

When `global = TRUE`, `geoscale` is ignored and [global\\_scales\(\)](#) is used by default.

The functions [sean\(\)](#) and [msean\(\)](#) perform the same sensitivity analysis, but they differ in their return value. The return value of [msean\(\)](#) is GeoNetwork, which contains the result from applying the [connectivity\(\)](#) function on the habitat connectivity indexes. Essentially, the risk maps.

If neither the inverse power law nor the negative exponential dispersal kernel is specified, the function will return an error.

In [msean\(\)](#), three spatRasters are produced with the following values. For each location in the area of interest, the mean in habitat connectivity across selected parameters is calculated. For each location in the area of interest, the variance in habitat connectivity across selected parameters is calculated. For each location in the area of interest, the difference between the rank of habitat connectivity and the rank of host density is calculated. By default, each of these spatRasters is plotted for visualization.

## Value

GeoRasters.

GeoNetwork.

# returns GeoNetwork object
mri <- msean(rast = avocado, global = FALSE, geoscale = c(-115, -75, 5, 32))
mri
```

---

search\_crop

*Search for crop*

---

## Description

It returns the dataset sources in which crop data is available. Essentially, a wrapper around [geodata::spamCrops\(\)](#) and [geodata::monfredaCrops\(\)](#)

## Usage

```
search_crop(name)
```

## Arguments

name	name of crop
------	--------------

## Value

Logical. Sources in crop data is available.

## See Also

[supported\\_sources\(\)](#)

## Examples

```
search_crop("coffee")
search_crop("wheat")

search_crop("jackfruit")
```

sensitivity\_analysis *Sensitivity analysis for habitat connectivity*

## Description

This function runs a sensitivity analysis on habitat connectivity calculated based on every combination of selected parameters. Parameter values in `sensitivity_analysis()` should be provided using the function `set_parameters()`. If no parameters are provided, then the `sensitivity_analysis()` function will run the sensitivity analysis using a default set of parameter values, which is accessible through the function `get_parameters()`. To customize parameter values, open the `parameters.yaml` that was automatically downloaded when geohabnet was installed, change, remove, or add parameter values directly in the `parameters.yaml` and save it. Once the values have been changed manually, run `set_parameters()` to set the new parameter values, which will return TRUE if the parameters were set successfully.

## Usage

```
sensitivity_analysis(maps = TRUE, alert = TRUE)
```

## Arguments

<code>maps</code>	logical. TRUE if maps of outcomes are to be plotted, FALSE otherwise. If TRUE, three maps are possible: a map of mean habitat connectivity, a map of variance of habitat connectivity, and a map of the difference between the ranks in habitat connectivity and habitat density.
<code>alert</code>	logical. TRUE if a beep sound is to be played once the analysis is completed, FALSE otherwise

## Details

For each location in a region, `sensitivity_analysis()` calculates the habitat connectivity risk index (CCRI) proposed by Xing et al. (2021). By default, `sensitivity_analysis()` runs a sensitivity analysis on a global extent, see `global_scales()` for details. This function also plots maps of the outcomes automatically, but it will suppress maps for outcomes if `maps = FALSE` or `interactive()` is FALSE. The returned object is of class `GeoNetwork`, which contains two types of outcomes. One outcome type corresponds to `spatRasters` representing the maps of habitat connectivity. The second type corresponds to adjacency matrices used to calculate the habitat connectivity, where columns and rows represent locations in the maps and entries are the relative likelihood of pathogen or pest movement between each pair of nodes.

**Value**

GeoNetwork. Errors are not handled.

**References**

ss3 <- sensitivity_analysis(TRUE, FALSE)
```

`setmaps, Gmap-method`     *Sets the map slots in the Gmap object.*

**Description**

This wraps the results(SpatRasters) from the risk analysis.

**Usage**

```
## S4 method for signature 'Gmap'
setmaps(x, me, vari, dif)
```

**Arguments**

<code>x</code>	A Gmap object.
<code>me</code>	A GeoRaster object representing mean risk index.
<code>vari</code>	A GeoRaster object representing variance.
<code>dif</code>	A GeoRaster object representing difference.

**Value**

A Gmap object.

**set\_global\_scales**      *Set global geographical extent*

**Description**

Set the geographical extents used in global analysis. Each extent should be in the form of c(Xmin, Xmax, Ymin, Ymax)

**Usage**

```
set_global_scales(value)
```

**Arguments**

value	list. Named list of eastern and western hemisphere extents. See usage.
-------	--

**Value**

List. Named list with scales for eastern and western hemisphere

**See Also**

[global\\_scales\(\)](#) [terra::ext\(\)](#)

**Examples**

```
set_global_scales(list(east = c(-24, 180, -58, 60), west = c(-140, -34, -58, 60)))
```

**set\_parameters**      *Set Parameters*

**Description**

This function allows you to set the parameters by replacing the existing parameters file with a new one. Use [get\\_parameters\(\)](#) to modify the parameter values.

**Usage**

```
set_parameters(new_params, iwindow = FALSE)
```

**Arguments**

new_params	The path to the new parameters file.
iwindow	Logical indicating whether to prompt the user to select the new parameters file using a file selection window. Defaults to FALSE.

**Value**

None

**Examples**

```
param_fp <- get_parameters()  
set_parameters(param_fp)
```

---

sp\_rast                   *Raster for mapspam crop.*

---

**Description**

get raster for crop in mapspam dataset

**Usage**

```
sp_rast(crp, africa = FALSE)
```

**Arguments**

crp	character. name of a crop. Case-insensitive.
africa	Fetch the 2017 Mpaspam crop data of Africa. Default is FALSE.

**Details**

See [geodata::spamCrops\(\)](#) for supported crops.

**Value**

SpatRaster

**References**

International Food Policy Research Institute, 2020. Spatially-Disaggregated Crop Production Statistics Data in Africa South of the Sahara for 2017. <doi: 10.7910/DVN/FSSKBW>, Harvard Data-verse, V2

sp_rast("potato", TRUE)
```

**supported\_metrics**      *Returns metrics currently supported in the analysis.*

## Description

Returns metrics currently supported in the analysis.

### Usage

```
supported_metrics()
```

### Value

vector of supported metrics.

## See Also

Other metrics: [nn\\_sum\(\)](#)

## Examples

```
supported_metrics()
```

**supported\_sources**      *Get supported sources of crops*

## Description

When provided, [cropharvest\\_rast\(\)](#) will look for cropland data in this specific source.

### Usage

```
supported_sources()
```

### Value

Vector of supported sources. Also used as a lookup to find get raster object.

## Examples

```
# Get currently supported sources
supported_sources()
```

---

tiff\_toRaster                    *Get raster object from tiffile*

---

## Description

This is a wrapper of `terra::rast()` and generates a raster object if provided with a TIF file.

## Usage

```
tiff_toRaster(path_to_tif)
```

## Arguments

path\_to\_tif        TIFF file. This is an encoding of map in raster format.

## Value

SpatRaster.

## Examples

```
# Generate raster for usage
fp <- paste(tempfile(), ".tif", sep = "")
ret <- utils::download.file(
  "https://geohabnet.s3.us-east-2.amazonaws.com/util-rasters/avocado_HarvestedAreaFraction.tif",
  destfile = fp, method = "auto", mode = "wb")
tiff_toRaster(fp)
```
