# Package 'footBayes'

August 31, 2023

Type Package

Title Fitting Bayesian and MLE Football Models

Version 0.2.0

Date 2023-08-25

Author Leonardo Egidi[aut, cre], Vasilis Palaskas[aut].

Maintainer Leonardo Egidi <legidi@units.it>

License GPL-2

Description This is the first package allowing for the estimation, visualization and prediction of the most well-known football models: double Poisson, bivariate Poisson, Skellam, student\_t, diagonal-inflated bivariate Poisson, and zero-inflated Skellam. The package allows Hamiltonian Monte Carlo (HMC) estimation through the underlying Stan environment and Maximum Likelihood estimation (MLE, for 'static' models only). The model construction relies on the most well-known football references, such as Dixon and Coles (1997) <doi:10.1111/1467-9876.00065>, Karlis and Ntzoufras (2003) <doi:10.1111/1467-9884.00366> and Egidi, Pauli and Torelli (2018) <doi:10.1177/1471082X18798414>.

# **Description**

All results for English soccer games in the top 4 tiers from 1888/89 season to 2021/22 season.

# Usage

england

# **Format**

A data frame with 203956 rows and 12 variables:

Date Date of match

Season Season of match - refers to starting year

home Home team

visitor Visiting team

FT Full-time result

hgoal Goals scored by home team

vgoal Goals scored by visiting team

division Division: 1,2,3,4 or 3N (Old 3-North) or 3S (Old 3-South)

tier Tier of football pyramid: 1,2,3,4

foot\_abilities 3

```
totgoal Total goals in game
goaldif Goal difference in game home goals - visitor goals
result Result: H-Home Win, A-Away Win, D-Draw
```

foot\_abilities

Plot football abilities from Stan and MLE models

# Description

Depicts teams' abilities either from the Stan models fitted via the stan\_foot function or from MLE models fitted via the mle\_foot function.

# Usage

```
foot_abilities(object, data, type = c("attack", "defense", "both"), team, ...)
```

# **Arguments**

object	An object either of class stanfit as given by stan_foot function or class list containing the Maximum Likelihood Estimates (MLE) for the model parameters fitted with mle_foot.
data	A data frame, or a matrix containing the following mandatory items: home team, away team, home goals, away goals.
type	Type of ability in Poisson models: one among "defense", "attack" or "both".
team	Valid team names.
	Optional graphical parameters.

# Value

Abilities plots for the selected teams: for Poisson models only, red denotes the attack, blue the defense.

# Author(s)

Leonardo Egidi <legidi@units.it>

foot_abilities(fit4, italy_2000_2002)
### seasonal dynamics, predict the last season
fit5 <-stan_foot(data = italy_2000_2002,</pre>
                       model="biv_pois", predict =306,
                       dynamic_type = "seasonal") # bivariate poisson
foot_abilities(fit5, italy_2000_2002)
## End(Not run)
```

 ${\sf foot\_prob}$ 

Plot football matches probabilities for out-of-sample football matches.

## **Description**

The function provides a table containing the home win, draw and away win probabilities for a bunch of out-of-sample matches as specified by stan\_foot or mle\_foot.

## Usage

```
foot_prob(object, data, home_team, away_team)
```

# **Arguments**

object	An object either of	class stanfit as given by	stan_foot function or list as
--------	---------------------	---------------------------	-------------------------------

given by mle\_foot.

data A data frame, or a matrix containing the following mandatory items: home team,

away team, home goals, away goals.

foot\_rank 5

home\_team The home team(s) for the predicted matches.

away\_team The away team(s) for the predicted matches.

#### **Details**

For Bayesian models fitted via stan\_foot the results probabilities are computed according to the simulation from the posterior predictive distribution of future (out-of-sample) matches. For MLE models fitted via the mle\_foot the probabilities are computed by simulating from the MLE estimates.

#### Value

A data.frame containing the number of out-of-sample matches specified through the argument predict passed either in the mle\_foot or in the stan\_foot function. For Bayesian Poisson models the function returns also the most likely outcome (mlo) and a posterior probability plot for the exact results.

#### Author(s)

Leonardo Egidi < legidi@units.it>

## **Examples**

foot\_rank

Rank and points predictions

## **Description**

Posterior predictive plots and final rank table for football seasons.

foot\_rank

## Usage

```
foot_rank(data, object, team_sel, visualize = c("aggregated", "individual"))
```

# **Arguments**

data A data frame, or a matrix containing the following mandatory items: home team,

away team, home goals, away goals.

object An object of class stanfit as given by stan\_foot function.

team\_sel Selected team(s). By default, all the teams are selected.

visualize Type of plot, default is "aggregated".

# **Details**

For Bayesian models fitted via stan\_foot the final rank tables are computed according to the simulation from the posterior predictive distribution of future (out-of-sample) matches. The dataset should refer to one or more seasons from a given national football league (Premier League, Serie A, La Liga, etc.).

#### Value

Final rank tables and plots with the predicted points for the selected teams as given by the models fitted via the stan\_foot function.

require(dplyr)

data("italy")
italy_1999_2000<- italy %>%
dplyr::select(Season, home, visitor, hgoal,vgoal) %>%
dplyr::filter(Season == "1999"|Season=="2000")

fit <- stan_foot(italy_1999_2000, "double_pois", iter = 200)
foot_rank(italy_1999_2000, fit)
foot_rank(italy_1999_2000, fit, visualize = "individual")

## End(Not run)</pre>
```

foot\_round\_robin 7

|--|

# **Description**

Posterior predictive probabilities for a football season in a round-robin format

# Usage

```
foot_round_robin(data, object, team_sel)
```

# **Arguments**

data A data frame, or a matrix containing the following mandatory items: home team,

away team, home goals, away goals.

object An object of class stanfit as given by stan\_foot function.

team\_sel Selected team(s). By default, all the teams are selected.

#### **Details**

For Bayesian models fitted via stan\_foot the round-robin table is computed according to the simulation from the posterior predictive distribution of future (out-of-sample) matches. The dataset should refer to one or more seasons from a given national football league (Premier League, Serie A, La Liga, etc.).

# Value

Round-robin plot with the home-win posterior probabilities computed from the ppd of the fitted model via the stan\_foot function.

italy

Italy league results 1934-2022

# Description

All results for Italian soccer games in the top tier from 1934/35 season to 2021/22 season.

# Usage

italy

## **Format**

A data frame with 27684 rows and 8 variables:

Date Date of match

Season Season of match - refers to starting year

home Home team

visitor Visiting team

FT Full-time result

hgoal Goals scored by home team

vgoal Goals scored by visiting team

tier Tier of football pyramid: 1

mle\_foot

Fit football models with Maximum Likelihood

# Description

ML football modelling for the most famous models: double Poisson, bivariate Poisson, Skellam and student t.

# Usage

```
mle_foot(data, model, predict, ...)
```

mle\_foot 9

## **Arguments**

data	A data frame, or a matrix containing the following mandatory items: season, home team, away team, home goals, away goals.
model	The type of model used to fit the data. One among the following: "double_pois", "biv_pois", "skellam", "student_t".
predict	The number of out-of-sample matches. If missing, the function returns the fit for the training set only.
	Optional arguments for MLE fit algorithms.

#### **Details**

See documentation of stan\_foot function for model details. MLE can be obtained only for static models, with no time-dependence. Likelihood optimization is performed via the BFGS method of the optim function.

#### Value

MLE and 95% profile likelihood deviance confidence intervals for the model's parameters: attack, defence, home effect and goals' correlation.

#### Author(s)

Leonardo Egidi <legidi@units.it>

italy <- as_tibble(italy)</pre>
```

10 pp\_foot

pp\_foot

Posterior predictive checks for football models

# **Description**

The function provides posterior predictive plots to check the adequacy of the Bayesian models as returned by the stan\_foot function.

# Usage

```
pp_foot(data, object, type = c("aggregated", "matches"), coverage = 0.95)
```

## **Arguments**

data	A data frame, or a matrix containing the following mandatory items: home team, away team, home goals, away goals.
object	An object of class stanfit as given by stan_foot function.
type	Type of plots, one among "aggregated" or "matches".
coverage	Argument to specify the width $1-\alpha$ of posterior probability intervals. Default is 0.95.

# Value

Posterior predictive plots: when "aggregated" (default) is selected, the function returns a frequency plot for some pre-selected goal-difference values, along with their correspondent Bayesian p-values, computed as  $Pr(y_rep \geq y)|y)$ , where  $y_rep$  is a data replication from the posterior predictive distribution (more details in Gelman et al., 2013). Bayesian p-values very close to 0 or 1 could exhibit possible model misfits.

When "matches" is selected an ordered-frequency plot for all the goal-differences in the considered matches is provided, along with the empirical Bayesian coverage at level  $1 - \alpha$ .

priors

Football priors distributions and options

# **Description**

This prior specification is just a duplicate of some of the priors used by the **rstanarm** package.

These prior distributions can be passed to the stan\_foot function, through the arguments prior and prior\_sd. See the vignette *Prior Distributions for rstanarm Models* for further details (to view the priors used for an existing model see prior\_summary). The default priors used in the **stan\_foot** modeling function are intended to be *weakly informative* in that they provide moderate regularlization and help stabilize computation.

You can choose between: normal, cauchy, laplace, student\_t.

#### Usage

```
normal(location = 0, scale = NULL, autoscale = TRUE)
student_t(df = 1, location = 0, scale = NULL, autoscale = TRUE)
cauchy(location = 0, scale = NULL, autoscale = TRUE)
laplace(location = 0, scale = NULL, autoscale = TRUE)
```

12 priors

## Arguments

location Prior location. In most cases, this is the prior mean, but for cauchy (which is

equivalent to student\_t with df=1), the mean does not exist and location is

the prior median. The default value is 0.

scale Prior scale. The default depends on the family (see **Details**).

autoscale A logical scalar, defaulting to TRUE.

df Prior degrees of freedom. The default is 1 for student\_t, in which case it is

equivalent to cauchy.

#### **Details**

The details depend on the family of the prior being used:

Student t family: Family members:

• normal(location, scale)

• student\_t(df, location, scale)

• cauchy(location, scale)

Each of these functions also takes an argument autoscale.

For the prior distribution for the intercept, location, scale, and df should be scalars. For the prior for the other coefficients they can either be vectors of length equal to the number of coefficients (not including the intercept), or they can be scalars, in which case they will be recycled to the appropriate length. As the degrees of freedom approaches infinity, the Student t distribution approaches the normal distribution and if the degrees of freedom are one, then the Student t distribution is the Cauchy distribution.

If scale is not specified it will default to 10 for the intercept and 2.5 for the other coefficients. If the autoscale argument is TRUE (the default), then the scales will be further adjusted as described above in the documentation of the autoscale argument in the **Arguments** section.

## Laplace family: Family members:

• laplace(location, scale)

Each of these functions also takes an argument autoscale.

The Laplace distribution is also known as the double-exponential distribution. It is a symmetric distribution with a sharp peak at its mean / median / mode and fairly long tails. This distribution can be motivated as a scale mixture of normal distributions and the remarks above about the normal distribution apply here as well.

#### Value

A named list to be used internally by the stan\_foot model fitting function.

# Author(s)

Leonardo Egidi < legidi@units.it>

# References

Gelman, A., Jakulin, A., Pittau, M. G., and Su, Y. (2008). A weakly informative default prior distribution for logistic and other regression models. *Annals of Applied Statistics*. 2(4), 1360–1383.

# See Also

The various vignettes for the **rstanarm** package also discuss and demonstrate the use of some of the supported prior distributions.

stan\_foot

Fit football models with Stan

# Description

Stan football modelling for the most famous models: double Poisson, bivariate Poisson, Skellam, student t, diagonal-inflated bivariate Poisson and zero-inflated Skellam.

# Usage

```
stan_foot(
  data,
  model,
  predict,
  ranking,
  dynamic_type,
  prior,
  prior_sd,
  ind_home = "TRUE",
  ...
)
```

# Arguments

data	A data frame, or a matrix containing the following mandatory items: season, home team, away team, home goals, away goals.
model	The type of Stan model used to fit the data. One among the following: "double_pois", "biv_pois", "skellam", "student_t", "diag_infl_biv_pois", "zero_infl_skellam".
predict	The number of out-of-sample matches. If missing, the function returns the fit for the training set only.
ranking	Eventual numeric ranking provided for the teams in the dataset (e.g., the Coca-Cola Fifa ranking)
dynamic_type	One among "weekly" or "seasonal" for weekly dynamic parameters or seasonal dynamic parameters.
prior	The prior distribution for the team-specific abilities. Possible choices: normal, student_t, cauchy, laplace. See the <b>rstanarm</b> for a deep overview and read the vignette <i>Prior Distributions for rstanarm Models</i>
prior_sd	The prior distribution for the team-specific standard deviations. See the prior argument for more details.
ind_home	Home effect (default is TRUE).

Optional parameters passed to the function in the rstan package. It is possibly

to specify iter, chains, cores, refresh, etc.

#### **Details**

Let  $(y_n^H, y_n^A)$  denote the observed number of goals scored by the home and the away team in the n-th game, respectively. A general bivariate Poisson model allowing for goals' correlation (Karlis & Ntzoufras, 2003) is the following:

$$\begin{split} Y_n^H, Y_n^A | \lambda_{1n}, \lambda_{2n}, \lambda_{3n} &\sim \mathsf{BivPoisson}(\lambda_{1n}, \lambda_{2n}, \lambda_{3n}) \\ \log(\lambda_{1n}) &= \mu + att_{h_n} + def_{a_n} \\ \log(\lambda_{2n}) &= att_{a_n} + def_{h_n} \\ \log(\lambda_{3n}) &= \beta_0, \end{split}$$

where the case  $\lambda_{3n}=0$  reduces to the double Poisson model (Baio & Blangiardo, 2010).  $\lambda_{1n},\lambda_{2n}$  represent the scoring rates for the home and the away team, respectively, where:  $\mu$  is the home effect; the parameters  $att_T$  and  $def_T$  represent the attack and the defence abilities, respectively, for each team  $T,T=1,\ldots,N_T$ ; the nested indexes  $h_n,a_n=1,\ldots,N_T$  denote the home and the away team playing in the n-th game, respectively. Attack/defence parameters are imposed a sum-to-zero constraint to achieve identifiability and assigned some weakly-informative prior distributions:

$$att_T \sim \mathcal{N}(\mu_{att}, \sigma_{att})$$
  
 $def_T \sim \mathcal{N}(\mu_{def}, \sigma_{def}),$ 

with hyperparameters  $\mu_{att}$ ,  $\sigma_{att}$ ,  $\mu_{def}$ ,  $\sigma_{def}$ .

Instead of using the marginal number of goals, another alternative is to modelling directly the score difference  $(y_n^H - y_n^A)$ . We can use the Poisson-difference distribution (or Skellam distribution) to model goal difference in the n-th match (Karlis & Ntzoufras, 2009):

$$y_n^H - y_n^A | \lambda_{1n}, \lambda_{2n} \sim PD(\lambda_{1n}, \lambda_{2n}),$$

and the scoring rates  $\lambda_{1n}$ ,  $\lambda_{2n}$  are unchanged with respect to the bivariate/double Poisson model. If we want to use a continue distribution, we can use a student t distribution with 7 degrees of freedom (Gelman, 2014):

$$y_n^H - y_n^A \sim t(7, ab_{h_n} - ab_{a(n)}, \sigma_y)$$
$$ab_t \sim \mathcal{N}(\mu + b \times prior \ score_t, sigma_{ab}).$$

where  $ab_t$  is the overall ability for the t-th team, whereas  $prior\_score_t$  is a prior measure of team's strength (for instance a ranking).

These model rely on the assumption of static parameters. However, we could assume dynamics in the attach/defence abilities (Owen, 2011; Egidi et al., 2018) in terms of weeks or seasons through the argument dynamic\_type. In such a framework, for a given number of times  $1, \ldots, \mathcal{T}$ , the models above would be unchanged, but the priors for the abilities parameters at each time  $\tau, \tau = 2, \ldots, \mathcal{T}$ , would be:

$$att_{T,\tau} \sim \mathcal{N}(att_{T,\tau-1}, \sigma_{att})$$
$$def_{T,\tau} \sim \mathcal{N}(def_{T,\tau-1}, \sigma_{def}),$$

whereas for  $\tau = 1$  we have:

$$att_{T,1} \sim \mathcal{N}(\mu_{att}, \sigma_{att})$$
  
 $def_{T,1} \sim \mathcal{N}(\mu_{def}, \sigma_{def}).$ 

Of course, the identifiability constraint must be imposed for each time  $\tau$ .

The current version of the package allows for the fit of a diagonal-inflated bivariate Poisson and a zero-inflated Skellam model in the spirit of (Karlis & Ntzoufras, 2003) to better capture draw occurrences. See the vignette for further details.

#### Value

An object of S4 class, stanfit-class.
